

POSTHUMOUS PAPERS

BEQUEATHED TO

THE HONOURABLE, THE EAST INDIA COMPANY,

AND

PRINTED BY ORDER OF THE GOVERNMENT OF BENGAL.

NOTULÆ AD PLANTAS ASIATICAS.

Part IV.

DICOTYLEDONOUS PLANTS.

BY THE LATE

WILLIAM GRIFFITH, Esq., F. L. S.

MEMBER OF THE IMPERIAL ACADEMY NATURÆ CURIOSORUM AT BONN CORRESPOND-
ING MEMBER OF THE ROYAL BOTANICAL SOCIETY OF RATISBON, OF THE ROYAL
ACADEMIES OF SCIENCE AT TURIN, AND CHRISTIANA HORTICULTURAL AND
ENTOMOLOGICAL SOCIETIES, AND SOCIETY OF ARTS, LONDON
MEMBER AND FOR SOME TIME VICE-PRESIDENT OF THE
AGRI-HORTICULTURAL SOCIETY OF INDIA.

*Assistant Surgeon on the Madras Establishment and a short time Officiating Superin-
tendent of the Honourable Company's Botanic Garden, Calcutta, and
subsequently Civil Assistant Surgeon, Malacca.*

ARRANGED BY

BY JOHN M'CLELLAND, F.L.S.,

Surgeon, Bengal Service.

Calcutta:

PRINTED BY CHARLES A. SFRRAO.

1854.

P R E F A C E.

WITH regard to the old opinion of spiral vessels being confined to flowering plants only, it may be remarked that they have been found in Lycopodiaceæ by Mr. Valentine. Indeed, they exist in abundance, simple and compound, in the gyrate portions of the rachis in many, perhaps all Filices; not that their presence depends on this gyration, but on the later development of these parts: since it is found that nothing but ducts are present in the older parts of many plants, while they occur with spiral vessels in the younger.

This was a mere assumption and until all and every link connected with the great chain be clearly defined, the distinction between flowering and flowerless, or rather sexual and esexual, is to be considered as artificial. We assume the constituent of the latter to be esexual because as yet we are thoroughly ignorant of their reproductive organs.

That the age of exogens may be known by the concentric circles exhibited by a section of the trunk, there are so many exceptions, particularly in tropical vegetation, that one may reasonably doubt its being the type or normal form of Exogens.

Cruciferæ.—From the examination of a species of *Sinapis* commonly cultivated throughout Assam for mustard and oil, my view of the structure is that the

order is dodicandrous. The stamina being arranged in 3 series of which the outermost is incomplete, the two lateral ones or those opposite the lateral sepals being alone developed, but they are still smaller than the others which form the intermediate series, and which are consequently opposite the petals. The innermost is represented by 4 glands evidently situated on the same plane, or forming a single verticel, and these are placed opposite the sepals, the two lateral ones being placed within the corresponding stamina. I attach considerable importance to the fact of the 2 stamina opposite the lateral sepals being invariably smaller, as it points out a tendency towards the total disappearance of the outer series. It will be seen that this view accords much with Mr. Lindley's: particularly as regards the incompleteness of the outer series.

With regard to the composition of the pistillum, I incline to Mr Lindley's opinion. I think that there are evident traces of 4 stigmata and consequently of as many styles: and these stigmata are so placed, namely, opposite the sepals, that the idea of their forming portions of two stigmata must be incorrect. If such were the case the line of division of either, should be opposite the lateral sepals.

I may here remark that this opinion seems to me to derive considerable strength from the consideration of the form and structure of the style, and its supply of vascular fascicles, these are 4, occupying the axis of the 4 angles. The centre is occupied by a transverse opaque line whether vascular or not, I am unable now to say. The number likewise of vascular fascicles occupying the axes of the component parts of the fruit

AGRICULTURAL RESEARCH INSTITUTE
PUSA

are 4. If the placentiferous valves were portions of the sterile (right and left) valves, such would not be the case. Then taking into consideration the want of continuity of structure between the two, I think there is very little doubt of the accuracy of Mr. Lindley's theory.

In *Thlaspi* I find traces, although obscure, of a quaternary division of the stigma, and as in the instance cited before, the divisions are opposite the sepals, a fact on which great stress is evidently to be laid. The alternation of the four larger stamens (which are opposite the anterior and posterior sepal) is obscure, still the anticus and posticus stamina, which should be opposite the placenta are evidently wanting, the smaller are as usual opposite the lateral sepals, while the glands instead of being opposite the sepals, are opposed to the petals. The larger stamina still seem to belong to the petals, some allowance being made for displacement. In this case the 5th series, or the second calycine one is totally wanting. Thus probably *Thlaspi* is 16 androus. The following numbers refer to the series as I have supposed them :

1. Sepals.
2. Petals.
3. Two lateral developed.
4. Glands.
5. Wanting.
6. Developed but displaced.
7. Carpellary leaves.

The style has 4 vascular fascicles and an opaque line in the centre.

In another, *Nasturtium* (Assam ~~Section~~ no. 454.)

a similar arrangement takes place, but a gland exists opposite the anterior and posterior sepal, so that the outermost series may be said to be more complete. There is no trace of a 4-nary division of the stigma, still I assume it from the transverse sulcus visible on the surface of the stigma dividing it into an anterior and posterior lobe, but I have not been able to ascertain the number of vascular fascicles of the style. The numbers refer as before.

1. Sepals.

2. Petals.

3. 2 glands, 2 stamens.

4. Glands.

5. Wanting.

6. Stamens.

7. Carpellary leaves. 1836.

Anonaceæ.—In the Ovulum of *Artabotrys odoratissimus* the foramine and secundine adhere, the latter has a fungous opening which projects beyond that of the primine

From a perfectly developed flower during impregnation, the ovary is 2-ovulata, ovulis basi loculi affixis *collateralibus*. 1835.

Magnoliaceæ.—In *Magnolia pumila* the ovula are situated transversely, that is, the raphe is not anterior or posterior, but lateral with respect only to the axis of the ovarium or the placenta. The secundine is quite distinct. The excavation of the nucleus is also very distinct. 1835.

Menispermæ —*Cissempeles* is a remarkable plant, and at one time I thought the female flowers to be dislocated, as it were formed on the same plan with the

males, and with four ovaria: the situation of the placental suture, which is anticous, is however an insuperable objection. The ovarium is never straight, nor is the incurvation of its apex gradual, but almost sudden. The spurious dessespement is a mere increase of growth of the placenta or rather of the part sustaining it, and it consequently does not consist of two plates. It is not a true drupe, since it is the testa which has become osseous, as is evident from the presence of the micropyle on it. In addition to which I have traced its development. The albumen is copious, and the radicle superior. The cotyledons are incumbent or rather they are opposite the narrow and true faces of the seed. The testa at a very early period (but after fecundation) has contracted an adhesion with the pericarp.

Dipterocarpeæ.—The saul, *Shorea robusta*, a gigantic *Dipterocarpus* exists in Upper Assam, lat. 28 N. Two species are found at Moulmein lat. 17 N. besides many other species representatives of other genera of this family.

Hamamelaceæ.—*Fothergilla* has the calyx truncate irregularly toothed. The filaments do not seem to be a multiple of the floral envelopes. They vary in number from 18 to 23 or 24. The anthers are quadrangular, not turned inwards and open longitudinally. The cells of the endothecum are ovate or globose, and the fibres well marked. In one case I found 2 filaments antheriferous proceeding from a common one, in that case the cohesion had taken place between 3, the central one being quite rudimentary. There are no sterile

anthers. DeCandolle suggests that the outer series may be transformed petals.

Petals are frequently transformed into stamina in *Bucklandia*, which is exstipulate. The anthers are *valvular* in *Sedgiwickia* and *Fothergilla*. The ovula are 12 in *Bucklandia*, the lower two of each cell becoming perfect seeds. They are indefinite in *Sedgiwickia* in which the lowermost only, and that not often, is perfected. Both these genera have the calyx of *Fothergilla* and the wood of *Coniferæ*. Mr. Lindley is mistaken in assigning deciduous valves to the anthers; this I think is mentioned by Mr. Brown as occurring only in *Hammallis sinensis*.

The valves of *Bucklandia* are very unequal, both are permanent. This genus is remarkable for having its buds which are always terminal enveloped in two scales, resembling much in form and situation stipulæ.

Halorageæ.—In *Mynophyllum tetrandium* Roxb., the seeds are arcuate and the embryo is necessarily curved.

Circæaceæ.—One species occurs on the Khasyah hills.

Rhizophoreæ.—The stamina in *Rhizophora mangle* are not twice the number of the petals but varying from 9 to 12. In *Rhizophora* as I limit it, they do not at all spring from the same points as the petals. The anthers in this genus are multilocellar the cuticle separating nearly throughout into anticous and posticous valves as the calyx is in some nearly inferior, the point cannot be always crowned by the calyx. The cotyledons are flat only in *Bruguiera* and perhaps in *Carallia*. In

Rhizophora and Bruguiera decandra the cotyledons are fleshy and capped by the original integument of the ovula; eight species of this genus are found on the Tenasserim coast only. Rhizophora and Bruguiera are natives of the shores of the tropics. Carallia is an inland marshy genus.

The peculiarity of the anthers was first hinted at by Jacquin and subsequently remarked upon by Mr. Brown, all others seem to have neglected it.

Melastomaceæ.—Although Mr. Brown in the appendix to Captain Tuckey's Voyage, first pointed out the peculiar situation of the anthers during æstivation, I may remark that it was not overlooked by Dr. Roxburgh, see his account of *Osbeckia tetandria* Flora India, vol. 2, p. 224. The manuscript of which is of a prior date to that of the Appendix.

In India this family is not limited to the tropics, *Sarcopyramis* of which at least 3 species exist is certainly extra tropical, so are some species of *Sonerila*, *Melastoma malabathrica* is found as far as 28 N. and most probably further.

Memecyleæ.—One species of *Memecylon* *M. pellucido punctatum*, has as its name denotes pellucid dots.

Mr. Brown's statement in Tuckey's Voyage, that this Order does not differ sufficiently from *Melastomaceæ*, is borne out by the existence of a Burmese genus. *Apterixis trinervis* M. in which the leaves are ribbed, and the fruit entirely melastomaceous although of a very peculiar structure, while the flowers exactly resemble those of *Memecylon*, with the exception of course of the ovary. The number 9 is of frequent occurrence

in the ovula of *Memecylon* and at one time I thought it to be so definitely.

Myrtaceæ.—It is difficult to reconcile the structure of the seeds of *Careya* and *Barringtonia*, but unless a reversion of the usual direction has taken place, they certainly are not dicotyledonous. The whole section should be removed from *Myrtaceæ* and raised to the rank of a distinct order.

Combretaceæ.—Mr. Brown's remarks upon this Order in his *Prod.* so it cannot be said to be without a character since a diagnosis is certainly given.

Species exist in India of *Pentaptera* and *Combretum* as far north as 28° N. lat.

The flowers of *Terminalia Bellerica* have a villanous sterco raceous odour.

Elæagneæ. This Order is certainly due to Mr. Brown, who first pointed out, that *Jussieus Elæagneæ* contained three very distinct Orders, *Santalaceæ*, *Elæagneæ* and *Combretaceæ*, and although he gives no character, yet an essential diagnosis is contained in his remarks : see *Santalaceæ*, *Prod.* 350-351.

The fruit of *Elæagne* is generally excessively sour and astringent. One species is eaten by the Burmese, and one by the Assamese.

Cytineæ.—Mr. Brown has himself confuted his original statement ; spiral vessels do exist in *Rafflesia*.

Santalaceæ.—The ovula of *Santalum album* differs from all others with which I am acquainted in the embryo being developed outside of the nucleus, and in the protrusion of what I call the albuminary membrane in the apex of which the first changes incident to fecundation take place.

Olacineæ.—Among two or three instances of coincidence of opinion with Mr. Brown, (I wish I could say there were more) without previous knowledge that such was the case, in my Mergui notulæ I referred Olax towards Santalaceæ, in which Notulæ a sketch of the structure of the ovarium will be found.

Stilagineæ.—To this Order belongs Roxburgh's *Ulmus integrifolia*. In habit and stipulation it certainly approaches to Cupuliferæ. In its ovarium, which however is always binarily composed, direction of it ovula their structure, and in habit it agrees with Euphorbiaceæ, especially in the presence of milky juice which occurs in a Nepalese and Bootan genus *Gymnobotrys*.

Salicineæ.—A few species occur in India within the tropics, one occurs about Calcutta, and two in the Tenasserim coast.

Hippocrateaceæ.—The trachea-like structure of the spiral vessels connecting the testa and cotyledons in Hippocratea, occurs in 2 Labiatæ, *Salvia verbenacea*, and one *Hyptis* a native of Madras. In both the tracheæ like threads are less highly developed than in *Collomia* and *Casuarina* in which last they are perhaps at the maximum.

Vitaceæ.—*Vitis* and *Cissus* do not differ according to Mr. Brown, all the species of the latter are to be referred to *Vitis*. The albumen is often rimose in which particular *Leea* agrees remarkably. This genus is certainly very nearly allied to this order, far more so than to *Meliaceæ* with which in the structure of its seeds it differs entirely.

Connaraceæ.—In *Eurycoma* (*longifolia* Jack) the ovula are erect. After flowering however the non abortive ovula is from an unequal growth of the ovary, carried upwards to such a degree that the seed becomes really pendulous.

Anacardiaceæ.—In *Anacardium*, the funiculus is lateral and even parietal. The ovula at a very early period is transverse with respect to the axis, neither the petals or stamens are perigynous, the stamens are hypogynous, the petals inserted into the fleshy base of the inflected portions. Dr. Sprengel wisely includes this genus in *Enneandria* although he says, *stamina decem*.

In *Mangifera*, the stamens are distinctly hypogynous and united at their bases into a short annulus. Into this just below the sinus of the stamens, the petals are inserted by a central spot, and not by the whole of their bases. In this genus also the ovule is fixed laterally; the funicle being adherent to the paries of the ovary. The foramen looks towards the bottom of the ovary.

In the *Diagnosis* the leaves are said to be without pellucid dots. Their definite stamens certainly do not distinguish them from *Leguminosæ*.

As the hypogynous insertion of *stamina* is certainly the most natural, no hypogynous order should have perigynous *stamina* ascribed to it because one genus happens to present an anomaly, and which Mr. Brown seems to think indicates a more perfect development. In *Syndesmis*, *Swintonia*, and *Melanorrhæa*, nothing can be more plain than the hypogynous insertion of the *stamina*.

The order is remarkable for a tendency to coalition of the petals with the stamina, which is carried to excess, as well as that of the stamina to the stalk of the ovarium in *Syndesmis*.

Coriariææ.—The raphe occupies that side of the ovulum, which is next the dorsal suture of the ovary. This is the case in the youngest stage in which I have examined it, but still most likely subsequent to impregnation. I cannot speak positively concerning any torsion of the funiculus, although in one or two instances a semitorsion certainly appeared to exist, I have one from the Abor hills. N. Lat. 28, 10; E. Long. 95, 20.

Balsamineæ.—The best proof of M. Kunth's views particularly regarding the spurred sepal being single, is derived from the position of the stamens, the 5th which is anticous being opposite the spur. It is the posticus sepal which is wanting. Jussieu in his remarks p. 270, hints at the real nature of the two exterior petals.

Violaceæ.—From a casual examination of an *Asam* species common in Lat. 28 N. I think that the study of the fecundation in *Viola* would be very interesting. It is difficult to imagine how the pollen gets access to the stigma, since this projects beyond the cone formed by the anthers for some time before the dehiscence of these organs takes place.

Amarantaceæ. *Digera* has the stamens opposite the sepals. The appendages existing in the axillæ of the lateral bractea are to be considered as modified buds.

Nyctagineæ.—The stamens in *Mirabilis* are originally hypogynous, that is before the tube of the calyx

becomes contracted above the ovarium. The contraction acts as a ligature, and actually presses into the filaments, though to ensure fecundation the upper filaments contract adhesions with the parietes of the calyx, the lower remain in the form of 5 subulate hypogynous processes, distinctly sphacelated at the apices. These process are visible in the ripe fruit on opening the indurated base of the calyx.

Chloranthaceæ.—To this order must be referred *Houttuynia*, the embryo of which is enclosed in a vitellus. It agrees with the order in every respect. The anatomy of the stem is decidedly dicotyledonous or rather exogenous.

The small bractes underneath each flower have been overlooked, and likewise the fact that the terminal flower of each spike is sub 7-androus, and that it is surrounded by several, 2-3-androus male flowers. Thence Thunberg's uncertainty as to its real situation in the sexual system; which may either be, judging from the terminal flower Heptandria, or Polyandria, or with still greater propriety Monœciæ.

Piperaceæ.—The statement of the flowers of *Piperaceæ* being hermaphrodite admits of much doubt, some species are certainly unisexual. It is likewise to be doubted whether all naked flowers are not unisexual.

The structure of the stem of *Piper* is certainly exogenous; both in the woody and herbaceous stems. These last exhibit in perfection the separation or rather the existence of two distinct systems composing the wood, and their complete separation, these may be called the fibro-vascular, and the fibrous. It is a

curious fact that the fibres of the former are always punctate; while those of the latter, are not: it is these only which are truly fibrous, the former being elongated cells. These true fibres exist in *Piper* either in distinct fascicles when they are contiguous to the fibro-vascular, from which they are always separated by soft cellular tissue, and they are always situated towards the circumference of the stem, or they form a continuous zone close to the bark.

This, in the genus under consideration is waxy, the latter formed fibro-vascular fascicles occupying the concavities; the convexities corresponding to the green lines so conspicuously visible in many species under the cellular integuments.

Podoslema.—From an examination of two species of *Podostemon*, I incline to the opinion of their being monocotyledonous, and that they are especially related to *Lemna* and *Pistia*. I have not however ascertained the existence of a foramen in the ovula, nor have I yet seen ripe seeds. From the invariably lateral situation of the stamina, and from the presence of abortive filamentose ones on the column formed by the cohesion of the filaments, I incline to think that the flowers are monæcious. In this genus a binary arrangement is strictly followed even in the formation of the pollen. One of the most striking features in this genus is its evascularity and in each axis of inflorescence being totally distinct. *Deboro, Feb. 18th 1836.*

Since the above was written I have ascertained *Podoslemon* to be dicotyledonous, its seeds are exalbuminous and orthotropous.

Two species are found on the Khasiya Hills, both are fixed to rocks or stones and both are half immersed.

Epacrideæ.—One species is found at Singapore which can scarcely be called or placed in Polynesia.

Campanulaceæ.—In *Codonopsis* and *Cyclocodon* a curious anomaly occurs. The parallel of which is to be looked for in Barclaya, I allude to the cohesion of the tube of the corolla to the ovarium, that such is the case I take it to be proved by the consideration of a Khasiya species *Cyclocodon distans*, in which the calyx is totally inferior and removed to some distance, from the base of the ovarium. M. A. Decandolle has I believe described what I call the calyx of *Codonopsis* as an involucre. but this view is not borne out by structure. *Deboro*, Feb. 28th, 1836.

Scævolea.—One species of *Scævola* occurs abundantly on the Tenasserim coast.

Three species occur in British Burma, between the parallels of 16,30 and 12th, Lat.

Cucurbitaceæ.—The anthers are one-celled at least in several of the genera. They are always extrorse.

There is no arillus, a genuine arillus is an extension of the funicle and never forms a perfectly closed sac round the seed. The "arillus" of *Cucurbitaceæ* is part of the placental tissue, it arises from the separation of the part immediately surrounding the seed, as this is its origin, it is at once evident, that it can only exist in those genera, which have the seeds immersed in the placenta. The seeds are completely naked in *Actinostemma* which has them pendulous

from the apex of a celled fruit. *Suddiya*, Augt. 13th, 1836.

Plumbaginea.—*Agialities rotundifolia* occurs in the Sunderbunds, and abundantly about Mergui, 12. N. Lat.

Composita.—Jussieu does not define his corymbiferæ so he says. “Flores vel flosculosi omnes, vel radiati.” See his observation upon the class page 167.

Cichoracea.—*Bellis* and *Carduus* are both referred here from inadvertence, *Carduus* is *Cynarocephalous* according to the author himself. Sec. supra *Carduus benedictus*. *Bellis* is *Corymbiferous*. The author may however intend the three as instances of each section, in which case there is no mistake.

Capripoliaceæ.—*Hedera* has the raphe internal! the cotyledons alternate with it and are hence accumbent: They are often however more or less oblique. July 14th, 1836.

In what does it differ from *Araliaceæ*. I know of no instance in which stomata are more abundant than on the upper surface of the leaves of *Hedera terebinthasæ*?

Loranthææ.—*Loranthus* differs from all other phænogamous plants in the entire absence of ovula until fecundation has been effected. *Viscum* is a little higher in the scale of development, but its ovula consist only of what I am disposed to call the albuminary coat: with this genus *Santalum* has especially in its placenta and ovula a good deal of relation with regard to their vegetation: the *stock* may be considered as unlimited, although it must be of a

permanent nature to ensure the maturity of the parasite: These plants are simply imbedded but there is no interchange of structure, unless in the case which not unfrequently happens of the sucker of one passing into that of an other belonging to the same plant.

Most of the accounts of the mode in which this parasitism occurs appear to be incorrect, at least most of the Indian species, are not confined to union by one spot. In these, roots are indefinitely thrown out, which contract unions with the stock indefinitely. *Deboro Mookh*, Feb. 29th, 1836.

Asclepiadææ.—The subject of impregnation in this order has been lately cleared up and pushed to an extent certainly unequalled in any other branch of organic Natural History. Brouginiart claims the honour of having discovered this, but I am inclined to give the whole credit to Dr. Brown, especially when we take into consideration one very great error into which Mr. Brouginiart has fallen, I allude to his statement of the dehiscence of the pollinias and consequent fecundation occurring in the cells of the anther. Mr. Brown has published his observations in the Linn. Soc. Transactions, in which however he had traced the tubes to, but not into, the ovula of *Calatropis gigantea*—and about the same time traced them to the placenta in *Hoya viridiflora*. Mr. Brown was the first who traced them into the ovula. He tells me that Treviranus had likewise succeeded. Wight has also succeeded in *Calatropis gigantea*. I have traced them to the same point in *Dischidia Rafflesiana* and *benghalensis*, part of my observations on which, I sent

to Mr. Brown in 1835.* With reference to this I claim the third place giving precedence to Mr. Brown and Treviranus; but no one but myself has hitherto traced them, I believe, in Asclepiadeous genera with erect pollinia.

I may add that *Dischidia* agrees exactly with the statement or description of the ovula of *Asclepeas*. *Deboro Mookh*, Feb. 29th, 1836.

Gentianeæ.—In *Sebæa*? the pollen is simple. The testa, which is simple is made up of sinuous cells. Feb. 23rd, 1833.

With *Villarsia*, *Parnassia* has many points in common in the situation of its stigmata with respect to the placentæ, and in the want of albumen. All these discrepancies may I think be explained. *Gubro*, March 12th, 1836.

Myrsineæ.—It is a common character of this order to have glandular, and even pellucidly dotted leaves. So much so that a shrubby plant out of flower with such and alternate exstipulate leaves, may with tolerable safety be referred to this order.

Samydeæ which agree in the above points are we are told by Dr. Brown distinguished by the mixture of linear and pellucid dots, but Dr. Wallich tells me that the same thing occurs in some *Myrsineæ*. *Deboro Mookh*, Feb. 29th, 1836.

I have since seen the union of the two sorts of glan-

* The subject is illustrated in an unique and most invaluable set of diagrams, constructed from his own original observations by the author, for the instruction of his Pupils in the Medical College of Calcutta, and deposited in the Museum of that Institution.

dular dots in a species of *Ardisiæ*. *Gubro*, *March 13th*, 1836.

Orobanchææ.—The testa of the seeds of *Ægine-tia indica* is composed of fibrous cells. The fibres being spirally arranged. *Mergui*, *Oct.* 1834.

Some cells of ordinary form being mixed up with them. I should add that these fibres do not exist in the ovula before fecundation has taken place. *Deboro Mookh*, *Feb. 29th*, 1836.

Cyrtandraceæ.—Mr. Brown makes this a tribe of *Gesnereæ*, see his remarks under *Aikinia*. With regard to the want of albumen I find traces of it in 3 species of the order, and if as I suspect there is in *Cyananthus* a tendency to union between the calyx and ovary, this appears to be no objection to the union of the order with *Gesnereæ*.

The embryo is certainly orthotropous. *Deb. Mookh*, *Feb. 29th*, 1836.

Verbenaceæ.—In the whole of that section to which *Congea* belongs, and of which the chief peculiarity consists in the capitate flowers and involucre, the placenta is central with 4 ovula hanging from near its apex.

With respect to M. Aug. St. Hilaire's assertion regarding the ovula being erect, I can only say, that *Vitex* has certainly pendulous ovula, *Avicennææ* is in all respects as genuine a constituent of this order as many of the section to which I have above alluded, and with which in the structure of its ovarium it agrees entirely.

Verbena has the 5th sepal posterior, the 5th petal is consequently anterior and it is external in æstivation.

The pistil is easily separable into two portions. The ovula are attached to the bottom of the cells, the foramen is inferior. The carpella are anterior and posterior: thence 2 of the cells are spurious and owing as in several others of the family to external productions of the placenta. The style has two vascular bundles, at the back of either stigma it is prolonged into a tooth-like process.

In *Zapania nudiflora*, the ovary is two celled. The ovula before fecundation are appense, but rather inclining to pendulous. The foramen is inferior, after fecundation the upper part of the ovulum undergoes the greater change and the ovulum hence becomes erect. *Burrumpootra*, April 2nd, 1836,

Labiatae.—The didynamy of some *Labiatae* differs from the usual form, in the upper pair of stamens being the longer. See the Mergui species of *Ocymoidea* described in the appendix of this volume. *Salvia verbenacea* has some what, the structure of *Collomia*. That is immersed in water abundance of spiral fibres make their appearance.

This fact I had ascertained in England certainly in 1831. It has since been mentioned as a new discovery in the Reports of the British Association. *De-boro Mookh*, Feb. 29th, 1836.

The style has two vascular fascicles, and at least in *Anisomeles* nearly the whole superior surface of the lobes of style so that the foramen is turned away towards the circumference, the stigmatic tissue is divided at the base of the style into four bundles one of which passes off to each ovarium. The

situation of the raphe is however in Boragineæ *Cynanchum* and *Myosotes* apparently reversed, the foramen being turned inwards, and pointing to the base of the style. But this instead of being an exception is a remarkably strong proof in favour of the universality of the law directing the situation of the raphe since in *Cynanchum* in which the ovaria subsequently become straight, the raphe is at length next the axis and almost, in all those in which the ovaria remain inverted; there is a similar tendency shewn by the radicle becoming superior, apex of the lobes of the style stigmatic, in *Gomphostemma* the raphe is next the axis.

Boragineæ.—In an Assamese genus nearly allied to *Cynoglossum*, the radicle is inferior. In another it is towards the situation of the foramen, which in all is inferior and on the inner side of the funicle, it undergoes no change. In all, the foramen communicates directly with this stigmatic tissue which forms the bulk of the style and is expanded at its base.

The umbilicus of *Myosotis* owes its origin to the channel of this communication becoming osseous and not being filled up. In the genus referred to above this is not the case and the umbilicus is a growth of the ovulum totally unconnected with fecundation. *Burrampooter, March 31st, 1836.*

Heliotropiæ.—*Heliotropium peruvianum* ovula.

Apparently reduced as in *Asclepiade* to one substance.

One species is common on sand banks in the river at Mergui and answers the same purpose which arun-

do arenaria and carex arenaria serve in Europe, and which might therefore be useful in binding artificial embankments

Gymnospermæ.—The pitted tissue is I believe not peculiar to Coniferæ, it occurs in Bucklandiæ and Sedgewikia and probably in all other Hamamelidiæ. *Deb. Mookh, Feb. 29th, 1836.*

Mr. Solly tells me that coniferous punctuation are likewise said to exist in Winteraceæ. June 29th, 1836.

Cycadeæ.—The trunk is in *Cycas circinalis* generally dichotomously branched. The same occurs in the Gowahatty species which is probably distinct. The second integument of the ovule is united to the outer, and so is the lower half of the nucleus to the corresponding portion of this. The margins of the foramen is callous and lucid: but no change, is effected by it on the pollen, which finds its way unchanged into a canal existing in the apex of the nucleus, and within which they emit tubes.

Too much stress has been, I think, laid upon the resemblance in the vessels so much insisted on by Brongniart, Mr. brown has remarked, that the natural state of *Cycadeæ* is to have many embryos. Judging, I suppose from the presence of the sacs existing in apex of the albumen, in this view he is as usual correct, it is a curious, fact that in *Cycas circinalis* and in the Assam species the alternate tessellations caused by the foliation and floration of distinct years is lost sight of in the undivided base of the trunk.

Within the albuminary membrane, and in the gelatinous fluid that it contains, the origin of cellular

tissue will perhaps by close observation be ascertained. This fluid abounds in active molecules.

Coniferæ.—Mr. Brown is certainly correct in stating *Gnetum* to have naked ovula : but here I think excepting its punctuations, the resemblance or affinity ceases, the nucleus has as I have shewn three coatings, but only at a certain period of its development. The use of this additional coat, the apperance of which is sudden, is evidently to ensure fecundation, still from the comparative rarity of development of the embryo this process is evidently but seldom or at least only under particular circumstances perfected.

Butomeæ.—*Butomus pygmæus* occurs abundantly in India from plains up to a height 2000ft. at least on the Khasiya hills.

Stomata exist on both sides of the leaf, the ovulum is anatropous, but the mature seeds closely resemble campulitropous. The embryonary sac although highly developed and apparently membranous presents traces of cellularity.

Burmanniæ.—Several species are so to say, aphyllous and such are very probably parasitical. From some observations on the structure of the seeds, I am led to conclude that the nucleus consist of several grumous masses, enclosed within a proper membrane I have not been able to ascertain the existence of any determinate form of embryo.

Orchideæ.—The filaments are adnate to the style.

With regards to the mode in which impregnation is stated to take place, I hope that certain distinguished botanists may change their ideas, which certainly are,

considering the thorough exposition of the true mode by Brown, unphilosophical. And according to the author's expressions how can the process be effected in those which have no gland whatever, the fact of the rare occurrence of fecundation in those genera which present great difficulties to its being effected, is at once an argument in favor of the gland, being a mere organ for favoring the removal of the pollinia. No great stress is ever to be laid on solitary characters, hence both Lindley and Bauer are wrong in placing so much reliance on the perforation of the pouches of Ophrys: the existence of which Mr. Brown appears to deny, additional proofs of fecundation occurring in the usual way have presented themselves to me in two genera in which from the imperfection of the lower wall of the clinandrium the masses are absolutely in contact with the stigma. In these as might be expected, this process was effectual and nearly universal.

Regarding their views as to the origin of the gland, and its nature, in addition to the proofs adduced by Brown of its being a portion of the stigma. I may say, that when no rostellum is formed, there is no gland. This is completely proved by the metamorphosis or rather deformity of a species of *Goodyera*, in which there is not a trace either of a rostellum or gland. But to insure fecundation a curious change of place occurred in the stigma, which instead of occupying the anticous face of the columna, had become posticous, occupying in fact the situation of the clinandrium.

Junceæ.—In an Assam species of *Juncus* agreeing remarkably well with the character of *J. prismatæ carpus* *Br. Pr. Ed. Nees*, 115. The flowers are imbracteate and the pollen ternarily compound. The ovaria are unilocular. This affords the second instance I know of, in which the secondine is exerted in the nearly ripe seeds. This membrane in the ovulum after fecundation, adheres to the apex of the nucleus, another unusual circumstance. The carpellary leaves alternate with the stamens, and as these are three, they are opposite to the inner sepals.

Aroideæ.—*Ambrosinia* of Roxb. *Cryptocoryne* of Fischer is remarkable for the structure of its anthers and embryo, the plumula of which is excessively developed. The development depending on the total separation of the cotyledon, as it were, by amputation, towards the maturity of the seed.

Pistiaceæ.—The organisation of *Pistia* is by no means simple, nor are the stem and leaves confounded; on the contrary, it has a distinct although depressed axis, highly developed leaves, but wanting stomata, and the spathes are distinctly pedunculate. In the scale of development it is far higher than *Lemna*: but inferior to it in having no stomata, superior in all other points, especially in *possessing spiral vessels*. Its cavities with cellular punctures are highly developed. Embryo at the apex of the albumen obovate, *solid*.

Equisetaceæ.—The affinity of this order, so far as the organs of fructification go, is with *Marchantia*. The four filaments are nothing but 2 elaters which adhere by their middles with the reproductive globule.

Without having been able to trace their formation to the requisite early period, I think it will be found that the sporules are formed with the cells of the endothecium which have spiral fibres. It is by the separation of these with the sporule that the appearance of 4 filaments arises.

The confervoid mass was, in the only species in which I have met with it, of considerable size, and always inequilateral. The first sheath has no stomata. The others have, they occupy the fundi of depressions, and are arranged linearly on either side of the angles, which are opposite to the teeth of the sheaths. Their component cells present the peculiar appearance of transverse bars. The sheaths are not separable from the axis except the lower one, and the apices of the rest.

Musci.—That the disk-like bodies produce, or are capable of producing young plants, as urged by some Botanists, is no proof that they originated from the male sacs.

No one can doubt, that impregnation is effected in this family, the constantly simultaneous appearance and dehiscence of the anthers at the time when the pistilla are formed, the constant sphacelation of the style, and the subsequent evolution of the nucleus or nucleary vesicle contained in the pistilla (or at least in that which produces the seta) are so much in common with the ordinary route of fecundation, that it is scarcely possible to believe, but that an analogous method is resorted. Here I may mention another fact of some importance, although occurring in *Hepaticæ*,

which is, that, in *Anthoceros* in which the evolution of the sporules is carried on in succession, or for a considerable period, after those first formed are matured, and have escaped; steps are taken to ensure a similar gradual succession of the male organs. The obvious difference is the apparent effect of the process in forming the seta analogous to the formation of pollen in some Aroidea and theca, not being limited as in Phanerogamæ to the evolution alone of the reproductive sporules or seeds. On these points Valentine has read a paper before the Linn Society, containing new views, and pointing out abundance of facts hitherto entirely overlooked by Cryptogamists; the anthers have no affinity of structure whatever with gemmæ. This is particularly observable in *Hepaticæ*.

Hepaticæ.—The common structure of the order is to have an original theca resembling much, that which is called the calyptra of mosses, and indeed differing only in never being torn up from its attachment. The only exception, I know of, to this occurs in *Anthoceros*, which appears not to have an original capsule, and consequently no calyptra. That which has been called a calyptra being nothing but a mass of tissue dislocated by the growth of the theca, I think also that *Marchantia* can have no calyptra, with regard to the secondary thecæ, they certainly present great differences; their place is supplied in *Riccia* by the original theca; are anomaly perhaps dependent on the immersion of the theca in the frond itself.

I have no more doubt about the impregnation of this order, than of mosses. The anthers of *Anthoceros* regularly dehisce at their apices, and discharge the mi-

nute granular matter, they contain a structure totally irreconcilable with the idea of their being gemmæ. The remains of these sacs may be always found in the cavities in which they are formed, and from which they cannot escape. This is the more remarkable as in *Riccia* the fruit always becomes exserted. I look upon the existence of the elaters as similar with that of fibrous cells of the endothecum; and I attach consequently very little importance to their existence.

The direction of growth consequent on fecundation is directly opposite to that of mosses, *Marchantia* and *Targionia* are remarkable for their stomata. The existence of which evidently depends upon their being furnished with a cuticle. This in *Riccia* is exceedingly rudimentary.

Characeæ.—Much light has been lately thrown on these obscure plants, particularly as regards their circulation by Varley, Solly and Slack.

The nucule is really monospermous.

REMARKS ON OVULA

An ovulum is, at its earliest period of existence an extension from some part of the surface of the placenta, it is at this time rounded sessile, entirely cellular, and without the slightest trace of any integuments. The first change that takes place is its separation to a greater or less extent from the placenta by the elongation of portion of this last, forming the funiculus, the next change is the marking out of its subsequent coat or coats by one or generally two lines of construction, the uppermost of which is however first formed, when two of these lines are formed, the ovulum is di-

vided into three parts, the uppermost which is generally conical and more transparent is the nucleus, the first developed portion, that which is contained between the two lines forms afterwards the second integument, the remainder of the base forming the outer coat or testa. But while these boundaries are being marked out, secondary changes may or may not be going on when the former is the case, it consists of a sort of inversion in direction of the ovule, by which the apex of the nucleus is brought towards the point of existence of the funicle from the placenta. The next step is the production upwards of the ring marked out between the two lines of construction, or one line only is formed by the production of the part immediately contiguous to the line, a ring is thus formed which embraces the base of the nucleus, shortly afterwards that which becomes the outer coat is similarly extended round the base of the second coat.

Both these continue to elongate, but the inner coat maintains for some time the ascendancy and at length entirely encloses the nucleus, beyond which it is generally continued into a neck variable in length, always open and generally somewhat dilated at its extremity.

The outer coat by its gradual extension at length likewise entirely encloses the nucleus, and the body of the inner integument, it frequently encloses the whole of this, while often before fecundation and for some time after the neck of this last projects to a considerable distance.*

* No one has enquired, how the base of the ovule is extended downwards, or how the base of the second coat extends downwards into the substance of the outer, does it or does it not?

Throughout the above period the nucleus has gone on increasing in size, but at the time of fecundation, it is invariably enclosed and concealed by both coats when the two exist. But it undergoes no further change for some period.

An ovulum at the time of fecundation will generally be found to consist of an outer coat open at its true apex, the opening varying in size, but always less than the diameter of the ovula; an inner cellular coat, generally thinner than the outer, prolonged beyond the nucleus into a hollow neck, the apex of which is open and more or less dilated, either (and perhaps generally,) about on a level with the opening of the outer coat, or projecting beyond it to a variable distance; and a central cellular body the nucleus, generally ovate, its apex being more laxly cellular than the remainder, and occasionally projecting into the neck of the inner or when this does not exist of the outer integument and in this case very much resembling a coat itself. At this period the ovula may be entirely cellular or it may be partly supplied with vessels, but I shall refer to this more fully when I speak of the raphe. The nucleus will at this period almost always be found to have a central discolored nucellus, or frequently an excavated cavity of varying dimensions. The above discoloration or rather opacity is invariably the precursor of the cavity that is about to be formed, and indicates the situation as well as the direction in which it will be formed. This cavity is always formed from below upwards.

All the subsequent changes at least those of any importance, are carried on within the nucleus. They

consist first of an extension of the cavity abovementioned, until with the exception of some few cases hereafter to be specified, this originally cellular thick solid body, is reduced to a thin coating, or even and not unfrequently reduced to nothing.

It will be seen that not one of these phenomena depend upon the completion of fecundation, nor in fact does any one, excepting the all important formation of the embryo, depend upon the due performance of this function.

The 4th change consists in the production of a membrane within the cavity already formed in the nucleus. To this sac, I attach very great importance, and I consequently shall be full in my details.

(*Compositæ*) whatever its nature may be, it appears to be always? formed from above downwards, that it is developed from the apex of the nucleary cavity: when completely developed, it invariably communicates with both apex and base of the excavation, the diameter being either uniform throughout, or larger at its apex, dividing by inferiorly into a thread of communication.

I know of no instance of the absence of this sac, of which from the consideration of *Viscum* and *Santalum*, I consider the only essential part of the ovula, preexistent to the embryo.

There are two curious modifications of this integument, and of great importance to study, and although the origin is in both cases the same, yet the growth is materially different, in the one, the albuminary form, consisting of the simple extension of a single cell, in the other, the exalbuminary form, of the growth of

additional distinct cellules from the surface of the original simple one. To the existence of the first modification, I find the presence of albumen invariably attached, so much so that in describing ovula, I would say with confidence whether the seeds would be albuminous or not. Even in those cases in which no opportunities have occurred of examining it aborigine, inspection of the margin of the sac will always settle the point, even although the whole of its inner surface may be occupied by cells, the rudiments of the future albumen.

The only instances in which albumen exists without this membranous sac is in those few cases in which that substance is deposited in the body of the nucleus, and the embryo is developed within a distinct sac (vitellus) which is always of the exalbumenary or membrano-cellular type.

In the exalbumenary form which in my descriptions. I term membrano-cellular in contradistinction to membranous, by which I characterize the albuminary form, the surface is even at a very early period distinctly cellular. This form may be seen to perfection in *Compositæ*.

Whatever its nature may be, as it invariably has important relations with the embryo, and as this is invariably formed within it, I propose calling it the embryonary sac.

Another important feature of this sac is its indestructibility, it always forms portion of the seed, although in the albumenary form, it occasionally becomes so identified with the albumen of the periphery,

that it is difficult to trace its existence. In the second modification its existence in the seed is always distinct, ex Composita, and Boragineæ.

The last stage in the development and the only one dependent upon fecundation, is the production of the embryo. This invariably consists in the appearance of a cell attached by a slight cellular pedicel to the apex of the embryonary sac, it is developed by the production of other additional cellules, which always contain much active molecular matter but less than the albumen. It soon becomes densely cellular in dicotyledons, the cotyledonary division is soon indicated, but the radicle is necessarily, from what I have just mentioned, the first part formed. With regard to the direction of the cotyledons, I have not as yet ascertained any law, they are often opposite to the true faces of the seed and often alternate. Embryos are generally axile when albumen is present, in those cases in which they are subsequently peripheral, this is owing to an equal deposition or formation of the albumen.

The albumen is of a comparatively early development, and when it exists is always partly formed before the embryo begins to appear, I find that with the exception of those cases in which the embryo is lodged within a vitellus that it is never formed within the nucleus.

In its earlier stages, it contains myriads of active molecules of a regular size, these molecules form in fact the milk of the albumen.

The presence of albumen is the test of an imperfect

embryonary evolution, or certainly of imperfect germinating powers, this though liable to some exceptions appears true enough; it explains why* albumen is so common among monocotyledones. Its presence is incompatible with the existence of a highly developed, plumula, a remarkable fact, and one particularly evident in some Aroidea which contrary to the habit of the order, have no albumen, the deficiency being supplied by a high degree of development of the Plumule.

The next point to be enquired into, is the relative duration of these coats, which are almost invariably 4 in number. The only instance, I as yet know of to the contrary occurring in *Xanthium*, in which there is a membranous sac, of excessive tenuity which lines the embryonary sac. These four coats the existence of which is possible are, the outer and inner integuments, the nucleary membrana, and the embryonary sac; of these the 1st is always permanent, remaining in the shape of the testa, as is likewise the embryonary sac. Traces of the two others are frequently imperceptible, and it may be expressed as a general rule, that the inner integument of the ovulum has no existence in the seed. This is well expressed by Dr. Lindley in his *Introduction to Botany*, p 184.

The nucleary membrane frequently exists, it is known from either of the preceding by being imper-

* Note—Mr. Brown long ago remarked, that albumen was the type of Monocotyledons, but no one has I believe remarked, that the proportions in favor of albumen among Dicot. Monopet. are nearly equal to those of Monocotyledons.

forate. On this point, Dr. Lindley has the following remarks. This third coat is formed by the proper membrane or cuticle of the nucleus from whose substance in the unimpregnated ovulum, it is never, I believe separable, &c. &c.

There is no positive mark by which the embryonary sac may be characterised as it is likewise imperforate. But its immediate contiguity to the embryo will in all exalbuminous seeds at once decide its nature: traces of its original attachment are likewise often visible at one of its extremities. The component cells in composita have a grumous nucleus.

I may here observe, that the seeds of this extensive family are not, at least in a great number of instances, akenia. In almost all I have examined. The outer tegument adheres to the cavity of the pericarpium, and in all separates with it. It is the embryonary sac that invests the embryo and separates with it. In albuminous seeds, as I have mentioned the existence of the embryonary sac is difficult to trace, this is owing to its having become incorporate as it were with the albumen. In others again its existence in the ripe seed is very distinct, enveloping the albumen in the shape of a hyaline membrane.

Various additions may take place on either surface of the outer integument, hence the number of coats is frequently apparently increased. M. Mirbel was the first to point this out.

With regard to the vascular supplies of the seed, I may remark that a sufficient number of observations, have not been made on the exact period of

the first extension of the vessels of the placenta into the ovulum. It is a general law that every part of a vegetable is aborigine cellular, the existence of a vascular system or of any system analogous to it in function being called into play at a subsequent period, and being a test in every sense of the word of complete evolution. Instances are not wanting where the seeds are certainly evascular, in others, the absence of vessels is supplied by elongated tissue. The vascular system of ovula is seldom, perhaps never complete until after fecundation, and it is very provable that the drawings which represent in such cases a distinct raphe are erroneous. It is most complete in those ovula in which the inversion above mentioned has taken place, the ovules anatropes of M. Mirbel. In most instances in which a vascular system does exist a direct communication is effected between the placenta and the base of the nucleus, around which in some instances the ultimate vessels in some radiate. It hence follows, that a raphe is not limited to the anatropous form of ovula, neither are the vessels confined to the testa, although it is an indisputable fact to which however I know of one exception? that the second integument (scarcely as it is not the second but probably the embryonary sac which is vascular) is, with the exception of that part of the base, perforated by the vessels in their course to the base of the nucleus, certainly cellular.

In those instances in which the base of the nucleus and of the integuments correspond with the

hilum it is often very short, its parts will of course depend on the distance between the above points.

The Raphe either consists of spiral vessels and ducts, or of ducts alone, and in some cases of elongated tissue. In the generality of instances, it terminates opposite the apex of the cotylidons, forming the chalayza, in some it becomes at this point bipartite, the divisions terminal towards either side of the true apex of the seed, as in *Carya* and some *Boragineæ*. In others it is continued unbranched terminating in, or towards the outer margin of the originally conspicuous foramen, as in many *Composita* and *Stylidium*.

Its situation may be regarded as universally next the ventral suture of the ovaria, or next the axis. For this important fact, we are indebted to Mr. Brown, who has likewise proved that all exceptions to this are only apparent, and originate in a torsion of the funicle subsequently to fecundation. The same distinguished author has brought this into play as a distinguishing character, and has pointed out, that true *Lonicereæ* may be at once distinguished from their allies by the reversion of the situation of the raphe. In this point of view it is useful, as proving that in *Boragineæ*, the ovaria are inverted, while in *Labiataæ* they are erect. In *Coriaria* it is dorsal, at least in one species from the Abor hills ; but I am at present unable to say, whether this arises from a twisting of the funicle or not.

In polycarpous ovaria, however there does not seem any fixed situation for the raphe. Thus in *Legumi-*

nosæ the foramen is uppermost and the raphe consequently lowermost; this was first pointed out to me by Mr. Brown, who immediately detected, that in my drawing of *Humboldtia* published in Dr. Wallich's *Pl. Asiat. Rariores*, I had reversed the situation. The same occurs in *Asclepiadeæ* and *Scrophularinææ*, and probably in most cases. In others again the foramen or raphal surface is lowermost, and in *Henslovia* it is indifferently lowermost or uppermost.

In some instances in which the nucleus coheres intimately with the outer integument, it seems to run rather between the two than in the integument, this is very evident on making a transverse section of the ovula of some *Compositæ*.

There is no appreciable difference of any importance between the development of the ovula in the two great divisions of *Phænogamæ*, excepting so far as the embryo is concerned. In both, the first steps in formation of this are the same. The same may be said of the *Gymnospermous* division of *Dicotyledons*, so far as I can judge from *Cycadeæ* and *Gnetaceæ*, the only two orders I have had an opportunity of examining it in.

I object to M. Mirbels' names which are founded on Numerical considerations; because in the first place, the precise number of coats is not always developed, and one cannot well call a coat the quartine when it is only the third. The names founded either on the parts from which they originate, or especially on physiological points, carry a certain amount of information with them, hence for the tercine I propose, that of nucleary membrane, and for the quartine I adopt M. Brong

nearly name, sac of the embryo, which is excellent in every respect. I am not acquainted with M. Mirbels' quartine; and I think it will be found that it is the embryonary sac, as well as his quintine.

It follows that the liquor amnios is never enclosed in the nucleus, it always exists in the early periods of the development of the sac of the embryo, and is certainly either the rudiments of albumen, or in exalbuminous seeds, of cellular tissue, which, by the subsequent enlargement of the embryo is pushed back and at length absorbed.

To repeat it, in all ovula no more coats than 4 exists. In Piperacæ, etc. in which an additional coat is supposed to be formed, it is merely the embronary sac.

The principal simple modifications of stigmata may be stated as follows :

1. Production of the midrib beyond the terminal sinus analogous to a mucronate leaf, it is evident that this may be carried to such an extent as to reduce the stigmatic surfaces to a mere point at the apparent base of the style.
2. Production of the stigmatic base beyond terminal sinus forming a bilobed stigma, the branches of this must be on the same place.
3. Obliteration of the terminal sinus, constituting an uniform stigma.
4. Obliteration of the inferior sinus.

I am not aware of any instance in which the stigma of a simple carpellary leaf is capitate, one sinus is always existing. There is however, on the principle, that both sinuses may be confluent, no theoretical

objection to the existence of such a form, although it would be reasonable to expect, that the axis of such a stigma would not correspond with the axis of the style.

Comparatively sudden reduction from a broad to a narrow surface is not uncommon in leaves, all apiculate or cuspidate leaves are instances, and of these, none can be more striking than that of the peepul.

But though a continuation of the placenta along either margin to the commencement of the apex of the midrib, would constitute the simplest form of stigma, yet it is still necessary to allow either an increase of the margins, or a spreading out of the stigmatic surface over the narrow part of the cauda or apiculus to explain those stigmatic lines which occupy the whole inner face of the style, excepting perhaps the midrib itself, such for instance as *Escholtzia*.

Stigmata are continuations upwards of the placentæ, they are consequently double, and have the same relation to the leaf as the placentæ.

There is perhaps scarcely a modification in the form of leaf, which may not be met with in an extensive examination of carpellary leaves.

Thus such instances of bilobed styles as occur in *Iris*, *Meyenia* etc., are representations of an emarginated bifid, or bilobed leaf, the true apex of the one is pointed out by the apex of the midrib, which is undivided, in the other by a protuberance, or when this is not evident by the termination of the central vascular bundle.

Bauhinia may be capable of explanation in three

ways, it is a simple bilobed leaf, or it is an abruptly pinnate bifoliate leaf, the leaves cohering by their inner margins, or it is a pinnate leaf, reduced to the two basal leaflets cohering with the costa of the pinna, this last is deserving of little consideration.

If it is a simple leaf, the midrib of the leaf as it exists should be the largest vascular fascicle, and all the other veins should be more or less lateral.

If an abruptly pinnate bifoliate leaf, cohering by the inner margin, the midrib will probably be the smallest, true midribs will exist for each lobe, and a mucronulus may be found terminating it: none may be found terminating the line of union.

To distinguish this from the third supposition, the line of union would probably be the most marked vascular fascicle of all, a mucronulus would exist, lateral mucronula might exist, and each lobe would have a central and largest vein.

I believe the first is the correct explanation, if so, the division or lobation may be carried nearly to the apex of the petiole, and this would be analogous strictly, for a mucro always exists,—instance *Labiatae* and *Boraginæ*.

I can also cite in reference to the similarity of modification between leaves and carpellary leaves, such instances as *Arum pertusum* and *Leonitice*.

M. Decandolles' hypothetical explanation of the degrees of division of leaves appears to me to rest upon very inefficient causes, one of which is easily disproved, because the degree of lobation ought to correspond with the distance between the primary veins.

This is only one of many instances of an attempt to reduce effects to causes.

We cannot explain every thing, in the present state of knowledge it is indispensable that effects should be referred to causes only when there is a manifest and a steady relation between two points of structure, which may be made to enter into the explanation.

To pressure for instance, many things are ascribed which are not due to it, and many things both our ignorance and knowledge are interested in ascribing to unknown causes.

A confession of ignorance cannot lead to error, while a subtle hypothesis especially by an eminent Savant may not only be false, but is very apt to check enquiry, from the assumption of knowledge contained in it.

NOTULÆ AD PLANTAS ASIATICAS.

PART IV.

Exogenous Plants.

CYCADACEÆ.

CYCAS.

THE species of this genus, with the exception of *C. revoluta*, are difficult to discriminate, so much so that the study of living plants at different stages is quite necessary to fix their differences. In habit and foliation, no practical marks are to be discovered, these appearing to be limited to the shape of the carpel leaf, especially the dilated apex, and to the figure of the fruit.

The anomaly of the upper part of the carpel leaf being broader than the rest: what does it indicate?

C. dilatata. The distinctions are very difficult, few if any practical ones can be taken from the leaves. I would derive them from the carpel leaves, particularly the lamina and its mode of division, the shape of the anther scales, the shape of the fruit, and the line of their points described by the leaves.

C. sphærica; fol. carpel. spith., parte nud. 6-uncialib. 3 ovulig., apice lanceolato-acuminatis e basin subulato-dentatis, conico-subulato dente squam. apiculo curvato æquant. fruct sphærica.

C. circinalis: apice squam. autem brevior subito. fol. carpel min. versus dist. ovulig. lamina subspath. a medio supra dentato-serrat, acumenato-subulat.

C. revoluta tot fol. carpel. gris toment., apice oblongis dilat. digitato-divisus, fruct. oblongo-rotund. villosa-pubescent.

Cycas.

External characters.

The trunk is simple, subexannulate, smooth in the lower and older parts, with the exception of irregular longitudinal fissures in the cuticle. In the later formed parts it is covered with the scars of the leaves, which scars of the leaves are arranged in indistinct annuli, the intermediate spaces being occupied by the remains of former inflorescences.

No stress is to be laid on the annuli, which are by no means universal, and which when present, are very obsolete. The trunk is proliferous, each year producing 2 close rows of leaves and terminal inflorescence, which necessarily becomes pushed out by the succeeding formation of leaves. These annuli may be traced from 5 to 7 formations, all traces of the scars of the leaves becoming lost after that time,

Dimensions: Erect, trunk 4 feet high, about a foot and half from its base, the circumference is $19\frac{1}{2}$ inches, and the diameter $5\frac{8}{10}$ inches; across the last formed annulus $20\frac{1}{2}$ inches; that of a trunk, 9 or 10 feet in length, (which was prostrate for about $\frac{2}{3}$ of its length, the inferior portion of the prostrate part had sent out several strong roots,) 1 foot from the crown of leaves 16 inches, around the last distinct annulus 15 inches, at the base of the erect part, the diameter $5\frac{1}{4}$. There is no distinction of bark, the great substance of the axis being composed of white dense cellular tissue.

The axis is occupied by pith of enormous dimensions, of close white cellular tissue; adjoining this, is a broad zone of fibrous wood of a yellowish brown colour. These zones vary in number from 2 to 3, and vary likewise in this, that they are close together, and are separated by white fibrous tissue.

The space between the outer zone which is small, and the cuticle is occupied by cellular tissue, white and dense, in

which are interspersed many very irregular bundles of woody matter. The pith is altogether similar to this portion; opposite each annulus or formation of leaves it is traversed by vessels.

Each formation of wood is connected by ligneous fascicles passing between each other. The inner woody formation is continuous, diminishing exceedingly at the apex of the trunk.

It is obvious from the small number of concentric circles compared with the formations of leaves, that these do not correspond, or rather that more than the wood of one formation of leaves enters into the composition of each circle.

In the prostrate trunk, the development of the wood was carried to excess on the decumbent side, on the opposite one there were three formations, the outer of which on reaching the commencement of the excentricity appeared to divide into 2. On this side 7 distinct formations may be counted, the last being exceedingly irregular from the woody matter passed freely into the roots.

No great knowledge of the structure of these remarkable parts will be attainable, but by close observation of all stages intermediate between that of the 1st development of the stem and its subsequent maturity. It is obvious that the woody matter is deposited in cones.

Connected with this excentricity there was no deviation in the regularity of the corona.

This is obvious if there are 3 zones in the lower, 2 in the centre, and one only at the apex. It is essentially exogenous, the latest fibres developed by the terminal, being always outermost: Dr. Mohls' statement appears to me to have nothing here to corroborate it.

Mr. Brongniant's opinion that the layers are not to be considered as analogous to the same number of layers of dicotyledonous wood, is also incorrect. What the relations are which these have with the epochs of inflorescence and foliation can only be cleared up, as he observes, by the examina-

tion of numerous individuals of different ages and different species. In all probability had he examined sections nearer the base of the axis, he would have found one or more additional layers,

In the fruit (Pl. CCCLXI. Fig. I.) which is of the shape and about the size of a hen's egg, the base of the papilla is still distinct, its mouth or canal being filled with whitish tissue, the rest being obliterated but still traceable by its brown colour. The nucleus has become osseous woody, and has lost its conoid shape, its apiculus is very small and bony. The next envelope is membranous with a flocculent rough surface, it is open at the summit, towards its base it is very thick and fungous. It adheres to the immediate envelope except at its apex. The immediate envelope is very thin, of a brownish colour, its apex is coniform and sphacelated, it corresponds to the centre of the perforation of the last envelope. The albumen is about the size of a pullet's egg, flattened at its base, there is a transverse irregular depression at its apex, it is heavy and fleshy.

In the more advanced fruit the quartine is separable from the tercine which has now become entirely fungous. The depression of the albumen is marked by 5 or 6 spots, which indicate the apices of so many cæca, which are either filled with mucilaginous fluid, or contain peculiar cellular bodies? With the exception of the cavities in which these sacs are lodged, the mass is entire and homogeneous.

The tardy development of the embryo is very remarkable. In the fruits I have examined some of which have been larger than duck's eggs, no trace of it has been visible. Mr. Brown first noticed the spots on the depressed surface of the albumen, and their correspondence with so many cavities containing sacs, which again contain a clear mucilaginous fluid, according to him they disappear, with the exception of one in which the embryo is developed. In the ovules there is some similarity with those of Gnetaceæ, the coats are however only four, no additional one being formed. The

chief difference is the adhesion of the secundine with the primine.

- a.* Second or drupaceous coat.
- b.* Third or fungous ditto,
- c.* Fourth or Neucleary ditto,
- d.* Outer coat.
- e.* Sac outer coat.
- f.* Albumen.
- g, h.* Central body its, depressed apex.
- i.* Transverse section of the apex of the albumen.*

In *Cycas circinalis* the ovuliferous leaves are of considerable thickness, flattened above, convexed beneath, and dilated towards the apices, the immediate apex being prolonged into an acumen. The upper half of the apex is deeply and sharply toothed, the ovules are arranged in cavities below the apex along with the margins, and more or less alternately. It is obvious that this arrangement would, if the margins of the leaves were produced inwards, produce a carpellum of normal male structure. The upper surface of the apex is invariably more or less smooth, the pubescence gradually disappearing as we proceed upwards, the immediate apex of the acumen is smooth, and corresponds to the stigmata of other plants, that is, when these are usually alternate with the placentæ.

The ovula are roundish, contained in the cup-shaped cavity, flattened obliquely above this, from right to left. They may be said to be obcordate; a papilla occupies the centre of the sinus. This papilla is short, cylindrical, truncate and open at the apex, the margins of the opening being somewhat thickened and shining, but apparently destitute of secretion. Their colour is polished greenish yellow and covered more or less with minute glaucido. A transverse

* *Cycas* perhaps is the most marked instance of perfection of mere fruit with fecundation, all the parts to the albumen being perfectly formed, and in abundance, for in *C. pectinatus*, apparently perfect specimens occur, all without embryos, the male being according to Major. Jenkins' exceedingly rare.

section discloses the following arrangement, a very thick coat, evidently and structurally divisible into two, the outer is thicker, having a distinct and thickish cutis, the remainder consisting of close parenchyma, of a green colour, and pierced with numerous irregularly disposed cavities which contain the mucilaginous matter, in which Cycadeæ so much abound, and which are analogous to the cavities in the outer coat of Gnetum, which are occupied by fibres of very large diameter. This coat or rather the outer part of it, is the primine. The inner portion is composed entirely of whitish dense tissue. This is the secundine, the vascular system consists of two fasciculi which occupy the inner part of the outer portion of tegument, running from base to apex.

The tissue of the secundine on a line with these fasciculi and between them, and the inner margin of the cavity in which the nucleus is contained, is arranged longitudinally. This portion of the coat is evascular, another reason for considering it to be primine. The central cavity is round, of considerable size and is occupied by a coniform fleshy cellular body, the cells being dense externally, rather lax internally, no vessels are traceable into this portion. The immediate centre is, if the section be made towards the apex, occupied by an opaque body.

June 8th, 1835.

1. *Cycas circinalis*. Pl. CCCLXI. Fig. II.

1. Female flower and portion of frond.

2. Ditto separated.

3. Ditto long section.

4. Ditto outer coats partially removed, shewing the free cone of the nucleus.

5. Ditto base of the nucleus and outer coats remaining, shewing the quartine of a globular form.

6. Quartine separated.

7. Portion of cellular pulp filling its cavity. At this stage

the two envelopes are altogether united, the papilliform process of the primine is open ; from its mouth a canal proceeds, which widens as it descends into a large cavity in which the cone of the nucleus is included, the apex of this is not exerted but terminates a little above the widening of the canal. The cone is solid, the base of the nucleus is occupied by a large globular cavity in which the sac of the quartine is contained. This sac is perfectly shut, and has no communication with the wall of the cavity of the nucleus. It is easily detached, is of a globular form and is filled with pulp, consisting of very lax, slightly angular cellular tissue of a perfectly homogeneous nature.

8. Ovule further advanced, the papilla of the primine has fallen off, and the canal is obliterated. No other change has taken place except in size.

It does not seem to me to come within the bounds of what we know of general structure, to reduce the male organs of *Cycas* to the type of an ordinary anther.*

Either each scale is to be considered as an anther, or each polliniferous bag is to be so considered.

All analogy is against the former, for no instance is known of the cells being distinct organs projecting beyond the surface. Though pluri-locular anthers are known; yet the cells are contained in the general substance of the anther, and at one period at least contained within its common covering or surface of that organ.

The ordinary type of an anther is 4-locular, the pollen is a separation or modification of the cellular tissue equally on both sides of the mesial line of the *leaf*: no instance is known in which the whole substance of the anther is so modified, except perhaps in *Sarcophyte*, but a part remains solid and unchanged as connectivum. Now in *Cycas* each polliniferous bag is a distinct organ, and the pollen is the entire modified cellular internal substance.

* No analogy between anther cells of *Cycas* and *Phænogs*.

There is no instance known in fact of an anther of 2-5 cells, each quite distinct from the other, and opening along their mutual inner surfaces.

But this aggregation, relation, degree and mode of dehiscence, together with the situation on the under side of the leaf, from which they are exclusively derived, are all points common to the reproductive (spores) of certain Cryptogams.

The first stage of development of the pollen observed, when the scales were—long—broad.

The pollen cells at this time are perfectly formed: those along the central line being the largest: they present faint traces of the line of subsequent opening. The cavity which is undivided, is one occupied by a loose mucilagino-cellular mass which is resolvable into angular grumous bodies, without distinct membrane, each presenting a cytoblast, or as I think, a point of commencement of the membrane. The development is, I think centripetal, *i. e.* the cells of the periphery are the most distinct.

There are also some remarkable points in the structure of the ovulum. The nucleus of the vegetable ovulum is always solid, up to the period of its being penetrated by the pollen-tube, it is homogeneous up to the period of the appearance of the embryo-sac. But in *Cycus* the conical apex is not solid, nor can it be said to be homogeneous, for it contains a conical cavity with a fundus presenting a central elevation, and its apex is produced into a cellular membrane which lines the canal of the foramen, and I believe adheres to it at its apex.

Then again when there is more than one appearance of embryo-sac,* their development is synchronous, but in *Cycas*

* They are not embryo-sacs. Embryo sacs do not exist for a long time after the enlargement of the fruit if there be no fecundation.

The appearances of the funicle of the ripe embryo is analogous to *Loranthus*.

What are the above sacs, which at any rate are developments of no

up to a late period, only one is to be found, containing homogeneous solid cellular tissue.

2. *Cycas Jenkinsiana*, Gr. Pls., CCCLX. Figs. 1, 2. CCCLXII. Fig. 1.

Trunk, often branched, sometimes 3 feet in diameter: in the specimen about 5 inches in diameter, marked externally with the persistent bases of the petioles, in some places almost annulated and nearly smooth. Here and there occur rings of smaller petiole bases, mixed with brown wool, marking the number of inflorescence.

Leaves about 4 feet long: naked lower part of the petiole 14 to 16 inches long, canaliculate, convex, with teeth-like straight solitary distant prickles along the margins. Pinnæ very many, 7 or 8 inches long, $3\frac{1}{2}$ lines broad, outline decidedly falcate, lower margin decurrent: they are very coriaceous, unequally and very obtusely emarginate, points almost always broken, with one stout vein prominent on both sides.

Female inflorescence forming a dense terminal head, surrounded by several rows of abortive leaves, subulate from a dilated base entirely covered with pale rust-colored wool. Carpel leaves erect, connivent, scarcely more than 5 inches long, of which nearly $\frac{1}{2}$ consists of a cordate acuminate lamina, deeply subulato-pectinate, the acumen stout and entire. In the upper half of the elaminal part are the ovula 1-2 in the outermost, 4-5 in the innermost. These carpel leaves are covered (except parts of the inner side of the lamina and the points of the pectinations) with dense rust-colored wool.

Ovula smooth, roundish compressed bases buried in niches (marginal) of the carpel leaves, with a distinct perforated apiculus.

impregnation. As these unimpregnated sacs are short confined to the apex of the fruit; how does the Embryo get so low down in the albumen? by percursion of the sac? or by enlargement of a particular one.

The crown of the immature fruit is broader, and depressed, so that the apex is rather concave. The carpel leaves are no longer erect, but the elaminate passes outwards, the lamina inwards, and this part is much broader and more concave.

The ripe seeds (only seen detached) elliptical, compressed, 18 lines long, 12 across the narrow diameter, 16 across the broad diameter; the apex presents a small apiculus, the base a large hilum. The epicarpium outside is smooth, of a yellowish brown colour; the mesocarp rather thick spongy-woolly, consisting of white cells at right angles with the drupe, between the two, there is a cellular white shining layer, sprinkled with resinous? reddish dots.

The inner surface of the drupe is lined by a papery brownish tissue with longitudinal vessel.

The albumen separates naked except at the apex, the surface of which is slightly furrowed, to which a thin brown membrane with a mamuilla in the centre adheres, underneath, there is a rather deep depression in the apex of the albumen, the fundus of this presents 6 greyish spots, to each of these corresponds an oblong cavity lined by a membranous sac.

Embryo very immature, attached by an enormously long curled up funicle, which arises from the union of 2 or more processes, passing down an equal number of the sacs.

HAB. Lower Assam, about Gowahatty, the specimens were obtained from Major Jenkins.

3. *Cycas pectinata*. Pl. CCCLX. Fig. 3.

Fruits disposed in terminal depressed heads, the carpel $1\frac{1}{2}$ foot in diameter not as in the others becoming spreading or in any way reflexed.

Carpels exceedingly numerous, allied in this respect to *C. revoluta* as also in occasionally narrow leaves, stalks about equal to the fruit-bearing part and apex included, spreading, beyond the fruit enlarged into a cordate lamina ascending and then incurved connivent and imbricated. All the parts

covered with dense brown tomentum, the points of the comb-teeth and the inner face of the upper ones being more or less smooth. Lamina approaches to that of *C. revoluta*, deeply pectinate, laciniae subulate, tapering into spinous points.

Fruits 2 to 4 alternating under the lamina, roundish, oblong, more or less angular from pressure, rich yellow, and at the apex, bearing a perforated mammilla.

Cycas revoluta. Thunb. agrees with (judging from Sir J. Smith fig. Linn. Trans. VI. t. 29, 30) *C. pectinata* in head of fruit, but the packing is not so close as to conceal all the fruit, as in *C. pectinata*. Then the hairs of the carpel, and the shape of the lamina are different, the pectines are irregular in direction, and deeper, some overlapping each other, lastly the fruit is hairy and red.

Cycas spherica is distinguishable in the Botanic Gardens, by a more feathery look of the crown, due to the pinnæ being less thick and opaque, none of the specimens have attained the size of *C. circinalis*, two males of which are very fine, and several times branched.*

4. *Cycas macrocarpa*, Griff., Pl. CCCLXII. Fig. II.

Petiolus crassus basi sub 4-angulatus, angulis lateralibus dentibus subulatis spinosis suboppositis horizontalibus vel leviter recurvis armat.

The upper part between the pinnulæ of either side is dark green, nearly the colour of the pinnulæ, and has stomatose spots. The under $\frac{1}{2}$ ditto is of the colour of the under half of the leaves, yellow green, and without stomata, although these organs only exist on the under surface of the pinnulæ.

Pinnulæ subopposite, vertical quoad petiol. margine infero subdecurrent. lineares subfalcatis curvatæ basi attenuatæ apici gradatim acuminatæ in subulam subpungent. costa

* *C. spherica* is distinct also in the shape of the male or anther scales.

utrinque prominula, subtus albida, ochroleuci margines recurvæ,

Length of the leaves altogether, some 8 feet, that of the Pinnulæ 1-foot 4 inches,

Breadth of ditto 5-6 lines.

The whole length of the fruit, *leaf* and all is between a span and a foot. The leaf, is covered with dense brown tomentum. The part above the fruits which are bifarious and so crowded as to touch each other, very short, triangular cuneate divided along edges into subulate subspinous teeth, of which the centre one is much the longest. The fruits are sessile surrounded at the base by a sort of annulus, which is not covered, with tomentum, elliptic, and the size of a duck's egg, viz. 2½ inches long, 1 inch 10 lines broad, so that the whole is heavy; colour green, subsequently yellow, at the centre of the subdepressed apex there is a brown mammillate point.

Insertion by a broad base, nearly the size of the annulus.

1. Outer tegument of short ochroleucous colour and disagreeable fleshy smell, 3 lines thick.
2. Then brown drupaceous coat of fusiform cellular fibres, in the middle it is harder both on outer and inner surface.
3. Then a thinish papery, vascular brownish coat.
4. The Embryonary coat but separating with the preceding (except at the apex where it is very thin membranous and shining, subapiculate and sphacelate at the apex).

The albumen is furrowed, and slightly furfaraceous outside, as also combined in 3 and 4; the inner face is of elliptic form, rather compressed, with a 4-angular depression at the apex, angles at the base presenting a foveola or slit, from each of which a shrivelled subelastica strap hangs, till they all conflux into one, no embryo formed, nor did I hear of any male flowers being known.

HAB. Crew between Ayer Punnus and Tabong: only on one spot and that near a Kuramut or Musulman tomb, so that it may have been introduced.

For my knowledge of this I am indebted to Mr. Wester-

hout, who tells me the trunk is 10-12 feet high, distinctly ringed and with short stout branches at the apex.

The upper part of each origin of the funicle is a closed cellular bag occupying a niche immediately under the foreola or slit above mentioned ; on the apex of this are two roundish detachable brownish cells ?

The funicles only occasionally adhere, they are 4 or as many as there are bags, they have a marked resemblance to those of the young embryo of *Loranthus*, they have no vessels, the large one contains longitudinal opaque air-bubbles. The flesh is divided by yellow tissue into two equal parts, the inner of them has the cells at right angles with the drupe, and they are longer.

Malayan name *Pakoo Galowe* : *September, 1842.*

SP. CHAR. Petiola sub 4-gono in parte nuda lateraliter spinoso. Pinnulis suboppositis linearibus in subulam gradatim attenuatis, margine recurvis, folio fructifero dense ferrugineo-tomentoso, apice breve triangularis cuneato-pinnatifida in subulas glabras, quarum centrale multo majore, fructibus dense congestis basi annulatis (magnis) ellipticis subcompressis.

HAB. Malacca at crew between Ayer Punnus and Tabong, near the Mahomedan tomb, specimens received from Mr. Westerhout.

The same *Cycas macrocarpa*.

Trunk 10-12 feet high, with distinct rings, and with stout short branches at the apex, (Mr. Westerhout). Leaves about 8 feet long.

The upper part between the Pinnæ is dark-green, like the upper surface of the pinnæ, and has stomata, the under corresponding part is yellow-green, like the under surface of the pinnæ, and has no stomata, although these organs only exist on the lower surface of the pinnæ.

Petiole stout, sub 4-angular at the base, the lateral angles armed with subopposite thorny straight or slightly recurved teeth. Pinnæ very numerous subopposite, linear subfalcate,

10-16 inches long, half an inch broad, alternate at the base where the lower edge is subdecurent, gradually acuminate towards the apex into a sub pungent subulate point, margins recurved.

Cone of male flowers about 13-14 inches long; the short stalk surrounded by subulate pungent-pointed abortive leaves, covered with rust-colored wool-scales cuneate, excluding the apiculus about 9 lines long, 6 lines across in the broadest part, upper margin thickened cartilaginous-looking, from its centre arises a subulate acumen retrofractedly ascending, $3\frac{1}{2}$ -4 lines long. Pollen cells in groups of 3-5 opening longitudinally along inner face.

Fruits crowded together into a terminal mass, intermixed with abortive leaves like those surrounding the male cone. Carpel leaves nodding 6-10 inches long, bearing the seeds about 4-5 inches from the base or abortive ovula, (these are sometimes as many as 8) beyond these expanded into a short triangular cuneate lamina, with pectinate edges, the central pectea being much the largest: where the seeds are attached expanded into sort of smooth annulus.* Seeds yellow elliptic (very large) 2-3 lines long, 17 lines across the short diameter, $18\frac{1}{2}$ across the longer. In the centre of the subdepressed apex is a brown mammillate point, the foramen. Hilum nearly as large as the annulus.

Outer tegument 3 lines thick composed of short ochroleucous flesh with a disagreeable smell. Drupaceous coat brown, composed of fusiform cellular fibres.

Inner tegument thinnish brown, papery, vascular. Third tegument separating with this except at the apex, where it is apiculate spicelated, thin membranous and shining.

Albumen with a quadrangular depression at the apex, angles, with a foveola or slit at the fundus. From each of these hangs a subelastic strap which all becomes confluent and gives attachment to the embryo.

* N. B. The left hand figures (Pl. CCCLX.) not numbered or named on the original drawing perhaps refer to this species. Ed.

5. *Cycas dilatata*.

Trunk about 5 inches in diameter, externally marked with persistent bases of the petioles but not equally so, for in some places it is annulated, and almost smooth, in others crowded with the bases of the petioles. Here and there a ring occurs of smaller petiole bases, mixed with brown wool, marking the periods of inflorescence.

Leaves about 4 feet long, the naked part of the petiole 14-16 inches long canaliculato-convex with teeth-like straight solitary distant prickles along the margins from abroad base.

Pinnæ 7-8 inches long, $3\frac{1}{2}$ lines broad, lower margin decurrence very coriaceous, unequally and very obtusely emarginate, points always appearing broken with one stout mid-vein prominent on both sides.

Female inflorescence forming a dense terminal crown surrounded by several rows of abortive leaves subulate from a dilation of the base, entirely covered with pale and cold tomentum.

Carpel leaves erect, ovule-bearing, dense part ferruginous woolly, beyond these dilatated into a smoother fleshy subcordate lamina, the margins deeply incised into subulate green long subpungent points, the apex broader entire subulately acuminate. The outermost bear no ovula: the next scarcely more than two.

There are about 4 ovula, on either side, close to the limb, the lower part of the petiole being naked.

Ovula attached by a broad base to a rather deep niche in the margin, about the size of a large pea, compressed, with a distinct apiculus, (the foramen).

A long section presents a central gelatinous body, surmounted by an apiculate brown cone, the apiculus of which corresponds with the foramen, the cone is hollow.

The crown of fruit (immature) is broader but so depressed at the apex as to be quite flat or almost concave. The carpel leaves are no longer erect, but curved, and the lamina is much broader and very concave.

The young seeds are oblong compressed 9 lines long by $8\frac{1}{2}$ wide, smooth, yellow, surmounted by a short reddish apiculus.

6. *Cycas* sp.

Truncus 4-5 rarius, 8 pedalis, vetustior vel basin versus exannulatis, apicem versus foliorum cicatribus notatus subannulatus, squamarum vestiguis inter annulos interjectis.

Petiolis basi incrassatis subteretibus utrinque lanceolatis.

Pinnulis linearibus angustis coriaceis, mucronato-acuminatis, decurrentibus inferior in spinas dentiformes reductis, quarum infimæ patentis, superior ascendentes.

Itinerary Notes. p. 141. No. 662.

AGATHIS.

The leaves of *Agathis* are directed obliquely upwards, their under surface is of a glaucous tint, arising from the presence of numerous stomata on their surface. The whitish tint of the surface on which these bodies occur, corroborates Dutrochet's statement, that the white spots are observable on some leaves, owing to the air contained in the adjacent tissue.

The leaves of this species are coriaceous lanceolate obtuse. They consist of a cuticle, especially dense on the upper or stomatous surface, and dense parenchyma, in which the green colouring matter is developed. Through the centre of this several parallel vascular fascicles, which do not anastomose run. The central ones of which alone, reach the apex, the others terminating at the margins.

The stomata have generally a transverse direction, and have direct communication with the inter-parenchymatous spaces.

The vascular fascicles consist of extremely elongated fibrous tissue, ducts and spiral vessels, which occur neither rarely, nor in a rudimentary state. It appears to me that none of the *peculiar* tissue exists in the young tissue of *Agathis*.

In the wood, these bodies occur generally in single rows in the tissue composing the wood, occasionally in double rows, the bodies alternating with each other.

From the arrangement of certain cells of the cutis and of the outer surface of the scales, of young cones, and which

corresponds to the lower surface of the leaves, there is an evident attempt at the formation of stomata: an additional argument in favour of the scales, being transformed leaves. But they likewise exist on the upper surfaces although in less numbers.

Agathis loranthifolia, Pl. CCCLXXX.

The ovula have when the cone is about the size of an egg only one tegument. They are much flattened, their largest diameter being transverse with regard to the axis, both the hilum and exostomium are obliquely situated, but still opposite to each other. The primine is of considerable thickness, cellular elongated in the direction of the spire, formed by the cone into an aliform expansion. The exostome is open, the nucleus is fleshy-cellular, it is entirely enclosed in the cavity of the testa, to the foramen of which its apex as usual corresponds. There is a very distinct central cavity, lining which there exists a fine membrane, containing some granular matter, and forming a sac which adheres slightly to the surrounding parietes, and which seems to be closed at both ends, certainly so inferiorly. It adheres very firmly to the apex of the nucleary cavity, and tears rather than separates.

At a later period when the seeds are $\frac{1}{2}$ of an inch long, their shape is considerably altered, the testa has become coriaceous, the exostome is still open. The nucleus is spongy and constricted at its apex. The membrane which I have above mentioned seems to have disappeared. The cavity of the nucleus is occupied by the nascent embryo of an oblong shape, constricted at both ends, this is pendulous, hanging from the narrow neck of the nucleus, the tissue of the lesser and lower constriction is the firmest.

1.—Fig. 1. Ovule of *Agathis loranthifolia*, about 1 line long, it is inverted.

2. Ditto part of testa removed, *a* testa, *b* nucleus.

3. Long section of nucleus, *a* embryo.
4. Nucleus more advanced.
5. Ditto long section, *a* embryo.
6. Embryo removed.

THUJA.

Thuja occidentalis, Pl. CCCLXXVIII. Fig. I, II, III.

The transition from the bracteæ clothing the peduncle of the galbulus of *Thuja occidentalis*, to the squamæ, is by no means abrupt.

In this genus there is a tendency towards completion of the carpella, the sides being prolonged beyond the real apex which is indicated by a prominence, the margins of which are transversely decurrent, if I may be allowed so strange an expression; judging from this tendency, we might expect to find a coniferous plant the seeds of which are not naked, in such a case, the fruit would be compound consisting of many simple single-seeded carpella.

The ovula in this genus are attached by a broad base, in a very young state they are marginal. The apex is attenuate the exostome large and irregular. The ovule is not very unlike a square flask. In all the specimens I examined, and which were all abortive, the primine was thick and osseous. The nucleus occupying the lower part of its cavity, being attached by a broad base. The apex is depressed and most distinctly areolate. At a later period and indeed when the galbulus appears perfect, the ovula are of considerable size, ovate, angular and somewhat curved. The testa is osseous and its exostome denticulate, the nucleus now occupies the

greater portion of its cavity, its apex is most distinctly depressed and discolored, the base of this part being rather constricted: no protrusion of the nucleus takes place.

The opening of the envelope or the exostome communicates freely by a canal of moderate size with the cavity in which the nucleus is lodged. The apex of this latter being prolonged as it were into the canal. The vesicula occupying that part which is opposite to the union of the secundine with the primine.

The fasciculus of vessels appears on a longitudinal section to run up between the outer and inner parts of the envelope, or between the primine and secundine. The base of the nucleus is confounded with that of the secundine. This body is free only superiorly, where it is half ovate, the apex being acuminate. The upper part consists of tissue, dense and whitish, while that towards the base is yellowish.

The apex is membranous and transparent, marking the excavated termination of a canal, which runs along the centre of the nucleus, nearly throughout its upper half. The apex is distinctly perforate, the base of this is truncate and filled with air and dislocated tissue.

Towards the upper part of the base of the nucleus or its united part, there exists a large globular cavity. This is lined by a very fine membrane which may be detached, and then presents the form of a globular membranous bag. It is filled with mucilaginous, grumous and granular matter, having distinct cells intermixed. I should say that on separation, the granules and enclosed cells form a sort of membranous body, probably by attraction, see fig. 7.

Six days after fertilization. No change with the exception of swelling that had taken place in the pollen, which was adhering to the outside of the ovule, after it had been applied for several days.

The pollen is frequently seen in the exostome, and in the instance figured the membranous perforated apex of the nucleus contained many granules, from which no boyaux had

been emitted. The rim of the exostome is particularly at this period shining.

No change appears to occur in the pollen while applied to the exostomium, nor does there appear to be in any instance an emission of boyaux. The exostome is frequently blocked up by pollen, in which no alteration has taken place. The nucleus is sphaecolated towards its apex and at the base of the membranous prolongation. The excavation in the apex of the nucleus seems to be cleaner, so to speak, sometime after the application of the pollen.

The boyaux are emitted as I suspected first from the firmness with which the grains of pollen adhere to the parietes of the excavation, which is absolutely crammed with granules of pollen. The boyaux are only generated towards the base of this canal.

There is nothing developed at this period, within the vitellus the parietes of which are a *perfect membrane*. This sac is filled with a fluid and grumous matter, in which last occur at considerable distances, distinct sacculi or cells. The grumous matter and the contained cells cohere and appear like a membrane.

The thecæ polliniferous are composed of tough membrane, apparently not cellular, marked with frequent lines obtuse occasionally clavate striæ, which are of a light brown colour, within this membrane there appears to exist a much finer membrane. There are no traces of the fibrous cells so frequent in the ordinary form of anther.

Eight days after fertilization.

The excavation of the nucleus is crowded with pollen granules, the great majority of which are with the exception of some tumefaction, unchanged. The parietes of the lower part of the cavity are *stigmatic*, that is the tissue is papillose and lax. The ovula are considerably enlarged, as is likewise the cavity of the nucleus. The vitellus is much more cellular.

The majority of granules have not generated boyaux. These appear to penetrate the lax papillose tissue with

which indeed they may be confounded. They are however at once known by the presence of granules in *their heads*, the *cells* being entirely destitute of these bodies. I may observe, that the boyaux appear to be confined to the truncated dilated bottom of the excavation. Their course cannot be traced unless by dissection; the tissue being exceedingly soft and rendered opaque by the pressure of even the thinnest mica. They are filled with granules, which are as usual of two sizes large and small, both being endowed with mobility but not in a high degree.

The tissue of the nucleus also surrounding the excavation, is now of a high brown colour.

I had set out with the supposition, deduced from observations on *Nelumbium* and *Crotalaria*, that there would be mere application of the pollen to the nucleus, and that no production of boyaux would take place. And I argued that the boyaux were produced in other plants in order to bring the surface of the pollen into contact with the nucleus, taking this view of the case, the granules would perform some other function, the mere nutrition of the containing membrane. It is now evident that mere contact of the pollen or of its tubes with the nucleus is not sufficient, as might indeed have been surmised from what takes place in *Asclepiadææ*. But that actual penetration of the boyaux into the substance of the nucleus is absolutely essential. The determination of the precise state of the pollinia at the period of the first appearance of the embryo, will throw great light upon this most intricate subject. If this does appear while the boyaux are appreciable, the tardiness of the appearance of the embryo in the *Mergue Cycas*, will depend upon impregnation not having taken place.

Ten days after. The excavation appears to be lined towards its base with a grumous mucilaginous fluid in which the pollen granules are immersed, at least this is the appearance that a longitudinal section presents. The boyaux have no apparent determinate direction, but penetrate the tissue at the base and

round the sides of the excavation. Then umber of granules contained in the visible parts of the boyaux, that is, in those parts which are not imbedded in the tissue is evidently much deminished, many of the grains of pollen which have not generated boyaux are nearly empty. Can these have excited any action on them? The Quintine is at this period tender, and is easily detached. It appears like a whitish ball of the size of a small pea. It is now distinctly cellular, the cells being exceedingly lax and of irregular figure, and hence does not collapse on the rupture of the cuticle, as it may now be termed. Mixed with the lax tissue are granular bodies, which perhaps may be the nuclei of the cells escaped on pressure, as they frequently occupy the axis of the cells. The bodies appear like sacs with irregular superficies, and contain many small granules.

The cellules of this sac are formed from without inward. Those of the periphery being in a state of cohesion, while the centre of the sac is occupied by fluid.

The outlines of the lately formed and distinct cells are exceedingly faint, even under a triplet $\frac{1}{35}$. These contain many granules which are in exceedingly active motion of a vibratory and rotatory nature, accompanied with very irregular and quick change of situation. These cells vary much in size, and in the larger which are of irregular outline, there is an evident, though faint tendency to subdivision. It is a most extraordinary fact, that these actually undergo slow changes of form, even when detached, and are still in the field of the microscope !

The indications of subdivision are merely owing to a greater aggregation of the globules. These bodies are particularly active in the new sacs, in which they are most transparent. There is some similarity between the appearance of these and of germinating sporules of *Marchantia*.

At this period, the sac is tense, and when pierced by a needle the contents are propelled to a considerable distance,

when the chief bulk of the sac is occupied by cellular tissue, the granules are still abundant, but they are stationary.

Connected with these observations, I should think that the development of the ovula of one carpellary leaf, occasionally varies much, the sac of the vitellus being at the period above mentioned, generally cellular, occasionally, nearly, or entirely liquid. Indeed the above observations relating to mobility and change of form occurred in an ovule, the others of whose carpellary leaf had cellular, or nearly cellular vitelli. —June 18th, 1835.

Thuja occidentalis, Pl. CCCLXXVIII. Figs. I., II.

- 1, 2, 3. Ovule of *Thuja occidentalis* from the same galbulus. The two former from the axillæ of the outer, the last from that of the inner scales.
 4. Ditto No. 3 long section.
 5. Nucleus detached.
 6. Ovule from a full sized ? galbulus.
 7. Ditto long section.

CUPRESSUS.

1. *Cupressus tortulosus* Pl. CCCLXXII. *Cupressus pendula*, *Abies Brunoniana* Gr. Itinerary Notes pp. 100, 131 Nos. 27 and 529.

a. micropyle, *b* wing, *c* ossified testa, *e* nucleus.

JUNIPERIS.

1. *Juniperis recurva*, Pls. CCCLXXIII. and CCCLXXIV. Male and Female : vide Itinerary, Notes p. 145. No. 696.

2. *Juniperis excelsa*, Pl. CCCLXXVII. Figs. 8, 8, 8a.

These figures represent a portion of the tissue of *juniperus excelsa*, of the Himalaya mountains. It is obvious that these supposed pores are ovate round bodies which are stuck across the cavity of the cells, or elongated

tissue in which they are developed. The ring inside corresponds exactly to the supposed opening in the containing cell. The irregular marks seen in the lower part of the sketch, are probably the remains of cellular tissue. This accords with Lindley's idea of this structure. It is certain, that apparently large holes are left in the containing tissue when these glands have fallen out. Lindley, however, passes over the central areola visible in the body itself *8a*, which uniformly transmits light of a yellowish green colour. My friend Valentine, who is unrivalled in delicacy of dissecting, shews this areola to arise from the presence of a glandular looking body of the above colour.

Pl. CCCLXXVII. Fig. 9, is an imaginary figure of this tissue, and will be at right angles with the preceding figure *8a*; it represents the membrane, which I suppose to be perforated opposite the axis of each body, viz., *b, b, b, b, b, b, b, b*, and is somewhat vesicular or rather raised up here; *d, d, d, d*, will represent the body transversely across the tube; *e, e, e*, etc., will represent the glandular yellowish body occupying the axis of *d, d, d*. This certainly accounts for the anomaly in a better manner than has hitherto been given.

This section is supposed to be carried through a portion of the tube, and through the axes of four bodies adhering to the tube.

Objection: two areolæ should be visible, looking vertically on the tissue, the areola of the containing membrane is that of the subexserted apex of the glandule.

The explanation of Dr. Mohl is obviously highly unsatisfactory, and has the disadvantage of giving no rational account whatever of this peculiar structure.

Section made at an angle of 45 present nothing but parallelogramic reticulations, the margins of which are ragged. *June 8th, 1835.*

TAXACEÆ.

Taxus, 2 sp. Pl. CCCLXXV. One with axillary the other with terminal inflorescence. Bootan collection.

EPHEDRA.

Pl. CCCLXXXI. Fig. 1.

The same organization prevails in the female flowers as in *Gnetum*: Mr. Brown originally affirmed the instances of truly naked ovula.

This genus is a remarkable one, and has marked analogies in certain important points with *Equisetum* and *Casuarina*? With the former its cuticle seems to perform the principal aërating functions, and it abounds in silex, the particles of which appear to have no definite arrangement, but occupy the disks of the stomata!

At least such is the supposition, I have for the present formed, it is easily proved by examining the surface at early periods, and the very young leaves, otherwise I can in the mature ramuli find no stomata.*

* I find that in *Ephedra Asparagina* Itinerary Notes, p. 340, no. 67, there is no deposition of silex in the cuticle, which has stomata, arranged as the discs of the siliceous species, longitudinally along the spaces between the bundles of elongated fibre.

So far my supposition is borne out.

This species approximates, to *Coniferæ* having generally whorled acerose leaves on its young branches.

The structure is exogenous, the wood has the usual markings, and is almost destitute of vessels, it is hence compact. The pith is from an early period, the receptacle of glandular secretions, which, when solidified, separate readily from their containing cells, whose form they almost necessarily have.

The bark is the part in which the aëration of green parenchyma takes place, it is thick and altogether green, except the gray cuticle, and contains rather numerous bundles of highly attenuated *woody* fibre; which bundles are approximated to the cuticle.

This last organ is papillose; the papillæ are irregular in size and distribution, but generally grouped in a certain order; these I take to be stomata, their disc is prominent greenish and separable in the form of subamorphous, *i. e.* scarcely crystalline masses which I take to be composed of silex.

The structure of the male flowers approaches in the perianth to *Gnetum*, but this covering is bipartite, the lobes covering each other closely, that next the axis or posterior being outermost. The anther presents nothing peculiar. That of the female (to one extensively acquainted with ovula) is not to be mistaken.

The outer coat is much like that of *Cycas*, and as in all such epericarpeal plants, is of sufficient substance to afford protection, *and sufficiently green to perform aëration.*

The inner membrane (like all the others) is elongated, but in excess, into a tube twisted towards the end which is more or less spatulate.

In it is a nucleus, with a depressed apex, of the usual cellular structure and appearance, and in this is developed the embryonary sac from above downwards, which sac is cellular, and so forms another exception to my practical rule for determining the future presence or absence of albumen from examination of the ovulum. Occasionally, in one instance, the presence of a toothed oblique cup was observed surrounding the axis, terminating which were two opposite bractææ, and one female flower.

The presence of an oblique scale round the base (on one side) of the ovule is common, but is generally if not always due to the separation of the scales above their bases on the application of force.

The character of this order in Lindley's Introduction, taken from Blume is open to considerable objections: of this the term projection applied to the attachment of the male flowers is one instance.

Then the female flowers are said to be sometimes sheltered by a false calyx consisting of two scales more or less combined, each of which surround one or two flowers a structure impossible, unless the scales are lobed, which they are not.

When two flowers are developed one may be axillary and the other terminal, or both axillary; when three, the relation they have to the scales and axis is obvious, when one, the axillary ones are abortive, because the plant is dichotomous, and in all such cases the terminal flower is developed first.

The style-like process is not formed from the membrane of the nucleus, in the sense here implied, or it is perfect before the nucleus is so, although probably originally formed from it.

Then no evidence is given about the protruded style-like process of the fruit before maturity, which process is the apex of the secundine, or inner coat. And with regard to the hypothesis assumed, it is totally contrary to all analogy, for in all instances in phænogamous plants when a pericarpial integument or pistillum exists, a stigma exists also. To this there is no exception.*

Then the assumption of the protrusion of the outer coat of the ovule is contrary to analogy, in all cases the tendency to this protrusion is greatest in the inner coat, the embryonary sac half filling the nucleus perfectly long before the an-

* Yet the female flower is far more præcocious MALES.

thers are perfected. Then the outer coat is rarely evascular, and as rarely if ever membranous, both which contingencies exist in *Ephedra*, if Blume's theory be adopted.

Lastly the perianth of *Ephedra* is not closed up, and is not eventually ruptured.

The remark of the more perfect evolution of *Gnetum* is a good one, and worthy of much attention.

It is a remarkable fact, and one that shews well the opposite directions of the growths of the male and female organs, that although the terminal spike is developed in both sexes, the terminal flower of the males is invariably absent, this however is most obvious in the organs of vegetation, particularly the leaves.

1. Portion of female inflorescence.
2. Female spike laid open.
3. Ditto at a younger period.
- 4, 5. Apparently abortive, the two inner scales, one of which is removed in fig. 4, were submembranous and not green, surrounding their common stalk was an oblique cup-shaped process.
6. Ovule detached, oblique scale on one side, probably the base of one of the decussate leaves or bractes.
7. Outer coat $\frac{1}{2}$ taken away.
8. Apex of the styliform elongation of inner membrane.
9. Both membranes partly removed shewing the nucleus
10. Nucleus detached.
11. Oblique view of its apex, as an opaque object.
12. Nucleus, surrounded partly about its base by the membranes, at a more advanced stage.
13. Nucleus, long section, shewing the embryonary sac. *ac*,
14. Embryonary sac, with its free apex imbedded in the base of the nucleus.
15. Portion of cuticle, stomata choked by siliceous matter.
16. Section of a branch of one year's growth.
17. Section of ditto of *Ephedra asparagina*, which has stomata of the ordinary sort.

Pollinia erecta oblonga compressa margine exteriori quoad glandula truncata, pellucida cartilaginea, stigma breviter apiculat.

HAB. In arborib. ad lilloram Maris. Ins. Madam. *Mergue*: *March*, 1835.

Hoya certe rudimentarum generarum includit quorum type sunt *Hoya viridiflora*, distincti polliniis non margine bruneatis coroneque foliolis. This is the same as no. 5, in *coronæ foliosis*, but distinct in *corollaque barbatis*.

4. *Hoya*? Pl. CCCLXXXVII.

1. Flower viewed in front.

2. Long section of do.

3. Corolla removed. Corona staminea exposed.

4. Section of corona staminea, Cal. Cor. Ovaria and styli removed, stigma remaining.
5. Part of the corona staminea, the processes cut off.
6. Pollen mass in front.
7. Follicula.

This is certainly not a true species of *Hoya*, although it is a congener of *Hoya viridiflora*.

HAB. Mergue.

5. *Hoya volubilis*, Pl. CCCCX. A. Fig. 3.

Scandens volubilis caulibus teretibus, foliis ovato-lanceolatis acutis coriaceis glaucescentibus basi, 1-callosis, indistincte 3-nerviis, umbellis intrapetiole longè pedunculatis, floris. Pedunculis perinnantibus, folia excedentibus apices versus cicatricibus inflorescentia antecedentis notatis. Pedicellis filiformibus $1\frac{1}{2}$ uncialibus basi minute bracteatis, masculis irregularibus purpureis, floribus magnis, albidis, *cereaceis* coronæ foliolorum angulis intrantibus. rosaceis, anth. lutescent.

Cal. 5 partit. Cor. subrotata profunde 5-partit. laciniis late ovatis acutis intus lucidis. Corona 5-phylla, foliolis carnosissimis, radiatis, supra planis, *ovatisque*, angulo intrante dentiforme in antheram product. incumbentemque. Antheræ membranum terminatæ. Pollinia erecta basi affixa, margine interiore quoad antheram, cartilagineam diaphanam. Stigma apiculo brevi, apice membranaceo.

Epiphytica in arborib. Mergue: *March*, 1835, flores sub-suaviter odorat.

The pollinia on being detached and especially if put in water become twisted, so that they have the same arrangement as those that are naturally pendulous. It is impossible to make them revert it to their natural situation. Very probably the fact of their being erect depends upon some local appreciable cause, to be ascertained by examination of these in the young state. *Æstivatio subvalvata, nec Hoya*

genuina civis ejusdem generis cum *Hoya viridiflora*. Partis floris interdum quaternaria.

6. *Hoya*.

Scandens radicansque in arboribus glabra, caulibus ramosis teretibus, foliis breviter petiolatis carnosis ovato-lanceolatis $1\frac{1}{2}$ uncialibus acutis subtus pallidis umbellis simplicibus, sæpius terminalibus aliquando subintrapetiole foliis longioribus Pedunculo perenni clavato, floribus albis dilutissimis rosei tincti, corollis barbatis revolutis, ciliis intra petiola. O. maculat, radicibus infra axillaribus follicul. brunnea.

HAB. Mergue. In sylvis *Madamacam*, August, 1834.

If this is a *Hoya*, *H. volubilis*, certainly constitutes a distinct genus, which may be distinguished as follows.

Cal. parvus 5-sepalus Cor. rotata reflexa. tubo brevissimo limbo superne barbato, corona staminea exserta 5-phylla, foliolis depressis carnosis ovatis, parte acutis in antheram, incumbendo, tubo duplici, corolla adnata, secundo omnino libero corollæ insidenti. Anth. membranacea terminata.

Pollinis erecta geniculis extrorsum processum gerentibus. Stigma obtuse apiculat. Folliculi gracilis. Sem. car-nosa.

7. *Hoya velutina*, Pl. CCCCX. A. Fig. 7.

Scandens pendula exarboribus, totam corollæ paginæ interiora excepta, pubescens.

Fol. oblongis basi subpeltato cordatis, acuminatis subobtusis margine recurvis coriaceo-carnosis obpendentum quasi resupinat.

Umbellis inter petiolaribus, plurifloris, pedicellis uncialibus clavatis, floribus amplissimis diametro $1\frac{1}{2}$ unciali albidis cereis, subinodoris.

Sepalis erectis majusculis oblongo cordatis.

Alabast. vertice depressa, 5-angulato, valvat.

Cor. rotata carnosae cereae, laciniis paullo infra medium product. triangularibus, margine revolutis nitent. glaber.

Corona foliola carnosae vertice planiuscula vel concava leviter subtus oblique, scooped away, angulo interior linguiforme centrum axeos attingens, margine membranaceo undulato. Anth. depresso-horizontalis margine membranaceo undulato.

Glandula brunneo-nitens. magna apice externo in setas leviter recurvatus product.

Caudiculæ planiusculæ sigmoideæ curvatæ longæ. Pollinia obovata, margine simplice. Styli disci capiat. in conum central. subclavat. radiato-striata.

Ovula plumina, placentam superficeam omneam externam convexam occupant.

HAB. Malacca. In sylvis littorat. Tangong Cling. An H. Velutina Wight Asclep. Lac copiosum. Flor. Febrio.

Asclepiadeæ. Gen. nov., Pl. CCCCIII.

Suffrutex volubilis, glaber. Caulis viridis compressiusculus linea pubescente alternatim notatus.

Fol. petiolata elliptico-ovata, basi obsoleto-cordata, breviter acuminata cum mucronulo integra, marginibus recurvis, superne atro-viridia sublucida minutissime puberula inferne pallida glabra, basi. 5-venia, venis lateralibus indistinctis, et glandularum conicarum seriebus duabus ima basi stipata, vena primaria secundariæ, tertiariæque paucæ infra prominulæ, ciistaque undulata membranacea insignita! V. secundariæ arcuatæ, tertiariæ variæ anastomosantes, quartariæ incospecuæ.

Petiolus crassus uncialis vel $1\frac{1}{2}$ uncialis supra planiusculus, subtus alato-carinatus, carina basin versus evanida.

Pagina infera tantum stomatosa.

Racemi subinter petiolares in umbellis spurias contracti. Pedunculo petiolo multoties brevior.

Pedicelli basi bracteas minuti suffult. pilis brevissimis brunnescentibus adpressis puberuli, ut etiam bracteæ, initio involuti! Flores inodori, mediocres, aurei, rubro-brunnei crebre punctulati. Corona staminea atro-purpurea, pili pennicillorum purpurei. Antheræ atro-brunneæ.

Calyx ordinis, sepalis 5 lanceolatis carnosiusculis, imbricatis.

Cor. rotata, profunde 5-partita, laciniae lanceolatae, carnosae mucronulo brevi viridi terminatae, dorso pubescentes, et punctulis subclavatis, sublentem notatae, aestivatione valvata, alabastra pentagona.

Corona staminea 5-phylla. Foliola carnosae concaviuscula cordata, extus bilamellata; lamella utraque acuminata apice pilorum rigidorum fasciculo-pennicillata, exterior longiore, intus dente obtuso, rugoso, stigmatis apice aequante aucta, sed in antheris nullo modo incumbente intus concavo.

Antherae membraceae: apici simplices, in stigmatis capiti arcte incumbentes, minutae.

Pollinia, basi affixa subtransversa, minutissima, rotundata *margini interiori* quoad par quodque exteriori quoad antheram truncata, hyalina. Glandula triangularis antice brunnea, postice pallida, caudulae semiopacae breves, latissimae, marginem superum totum glandulae occupantes.

Stigma apice depressum planissimum muticum; interdum obsoletissime bimucronatum. Ovarium ordinis; ovula ascendencia oblonga, foramine sulciformi. biseriata.

Placentae extrorsum productae in lamellam loculorum parietibus applicitam et ovula fere obtegentem,

HAB. In sylvis, *Suddiya: Upper Assam, July, 1836.*

Genus certe novum: Hoyae notis quibusdam affine; distinctissimum ob corollam aestivatione valvatam, foramen foliorum coronae stamineae stigma depressum, et ovula biserialia; structure in ordine mihi plane ignota.

1. Alabastrum first before expansion.
2. Section of corolla shewing its valvate aestivation.
3. Flower.
4. Ditto corolla removed, miserably out of perspective, the inner process of the back foliole not shewn.
5. Vertical view of corona staminea and stigma.
6. Ditto two of the foliola, bent back with their anthers shewing the situation of the pollinia.

7. Apex of corona lateral view, foliole removed, shewing the very small clefts, by which the pollen tubes would at a pass down to the apex of the style.
8. Pollinia pair of, viewed in situ and looking vertically down on the stigma.
9. Ditto in situ, but viewed rather laterally.
10. Same as 8, but the furrow is wrong, this is only visible on the outer angle or base of the gland.
11. Pollinia viewed laterally.
12. Pollinia, same as 8, furrow wrong; the masses displaced.
13. Pistillum, one of the ovaria laid open longitudinally to shew the extention of the sides of the placenta.
14. Ditto vertical view, ovula bases of, only visible.
15. Ovary transverse section, ovula nearly enclosed by the convolute placenta.
16. Ovary cut down longitudinally, parietes for the most part removed, shews the direction of the ovula of one row, and the relative situation of the groove and raphal face, no raphe exists at the time of flowering.
17. Ovulum.
18. Apex of one of the laminæ of the foliole of corona staminea.

PERGULARIA.

Pergularia minor.

Caulis scandens teres, pubescens, folia petiolata ovato-cordata acuminata basi 3-nervia, reticulatim venosa, nervo medio basi corpora 3-5 brunnea gerento; cymis paucifloris intra petiolares; pedunculo communi petiolis duplo brevioribus, pedicellisque pubescentibus, flores majusculi pallidi lutescenti-virides fere inodores.

Cal. 5-sepalus, sepalis lanceolatis subæqualibus. Cor. tubus longitudine fere sepalorum, ovatus teres, fauce constricta, limbus sub erectus, laciniis 5, oblonga laciniatis, marginibus revolutis æstivatione contortis. Corona staminea 5-phylla, foliolis

extrossum complanatis, apicem infra subiter in processum subulatam in super antheram incumbentem et stigma paulo superantem angustata, processis in paginæ interioris folioli prominulo (an nervo medio folii analogo.)

Antheræ membrana maxima productæ in super stigma conniventes, biloculares, loculis ratione membranæ minimis

Pollinia (Pl. CCCLXXXVI.A. Fig. XIII.), erecta oblonga vix compressa, deorsum infra insertionem caudiculæ externe breviterque product. an margo dehiscentibus. Caudiculi breves. Stigma muticum oblongum crassum, transverse sulcato, apice celluloso albido quasi fungoso. Folliculi ovato-subulati. Semina valde compressa subulata ad hilum comosa.

Embryo immaturus orthotropus. Cotyledoni suborbiculæ venosæ. Placenta multa alata alis tenuissimis.

HAB. Bengal. Legi. in sylvam ad ripas *Jellinghey prope*, 1845.

This seems to be the *Pergularia minor* of Andrews Repos. Tab. 85, and *Asclepias pallida* Roxb. Fl. Indica 2. p. 48.

DISCHIDIA.*

1. *Dischidia Brunoniana*, Gr. Pl. CCCCX. A. Fig. 1.

Epiphytica in arborib, caulis arcte prostrata repentis et ad articulos radicans verrucosis, verrucis apicibus, piliferis.

Fol. breviter petiolatis suborbicularis, subpeltatis abrupte breviterque acuminatis carnosis supera infera planiuscula, supera rugosa verrucosa pilosaque, umbellis intra petiolibus paucifloris pedunculis viridiscentis verrucosa pilosa, foliis brevioribus, floribus magnis, tubo saturato-sanguineo limbo rosaceo: odor 0. Pedicellis brevib. calycibusque carneis.

* Plates CCCXC, CCCXCI, CCCXCII and CCCXIII, are illustrative of the impregnation of *Dischidia*. The author's remarks on the subject are here omitted as they have been recently published in the Transactions of the Linnæan Society, Vol. XX., p. 391.

Cor. urceolata 5-partita laciniis ovatis erecto-patentibus medio bases versus longitud. carnosis crassis, sinubus introsis in gibberibus productis, æstivatio valvata, fauce scabris pilosis clausis, pilis ascendentibus *medio punjentibus*.

Corona 5-phylla, foliolis stipitatis limbo subverticalis reniformis albis, fissuris hiantibus fusco-purpureis. Anth. concolores membranaceæ marginatæ terminaterque.

Pollinia erecto-oblonga valde compressa citrina, glandula brunnea, geniculis glandula superant. rubro-brunneis. Stigma apiculo longiusculo subulato.

Species distinctissime obscuritatem. Cor. lacinia erecto-patentis nec conniventissimis gibberiformis, corona foliolis marginatis reniformibus nec bilobis hippocrepidiformibus.

HAB. Mergue. Inter Rhizophoreis. Ins. Madamacam Palor prope.

2. *Dischidia (Leptostemma) coccinea*, Gr. Pl. CCCCIX.

Repens radicansque in arboribus. Caulibus in parte floriferis sæpius foliis orbatis.

Fol. (insignia) ramulos arcte circumvoluta ideoque subtus concava (ibidemque radiculos ramosas foventia) subpeltatum affixa reniformi-cordata, sinu in processum pyramido-dentiformem, superne elevato, verrucis conicis parce exasperat. supra fusco-viridescencia, subtus purpurea seniores alba oblecta.

Umbellis paucifloris.

Floribus urceolatis, tubo obtuse pentagono coccineo, limbo brevi vulvat. connivent. livide brunneo, faux annulo incomplete clausa. Coronæ foliolorum *laminæ cordatæ*.

Pollinia compressa, spatulato oblonga caudicula brevissima.

Foliculis (juniorib.) extrorsum arcuatis, *interne convexiusculis* longiuscule rostratis.

HAB. In arbor Terebinthæ, Malacca. A remarkable species explanatory of *Dischidia Rafflesiana*, so far as the ascidia and radicles of that species are concerned.

To this genus belongs *D. Rafflesiana*?

All the leaves have the same direction, and are subimbriate;—very irregular-looking for such organs.

Spec. Char.

Folhis reniformi-cordatis, supra verrucosis in ramulis circumvolutio adpressis, sinu pyramidali, floribus coccineis laciniiis brevibus rotundato-oblongis, fauce annulo semiclausa. Caudiculis polliniis spathulato-oblongis multoties breviorib.

3. *Dischidia*, (*Leptostemma*) *albidum*. Gr.

Radicans et repens in arboribus. Caulibus filiformibus.

Foliis cordato-ovatis, mucronulatis subaveniis, breve petiolatis, utrinque (sed supra magis) convexis ideo carnosissimis, supra pallidis subtus quasi albo-brunosis.

Pedunculis subaxillaribus, perennant. petiolorum longitudin.

Floribus umbellatis, paucis, inconspicuis albis.

Cor. urceolata, limbo longiusculo valvato coniform. coniformi-connivens.

Faux villis transversis albis clausa, coronæ foliorum laminæ angustæ spathulatæ carinatæ.

Caudiculæ pollinæ æquantes. Polinia oblonga vix compressa.

Folliculis secus internum faciem profunde canaliculatis longissime rostratis fusciscent.

Semina coma tenuissim. longissim.

HAB. In arboribus Malacca, vulgatum.

Spec. Char.

Leptostemma albidum foliis cordato-ovatis, mucronatis juniorib. utrinque convexis, velustior planiusculis laciinis corollæ tubum fere æquantibus fauce villis clausa, folliculis longe rostratis.

Of this genus I have met with three species, all agreeing in habit, shape and æstivation of corolla, and peculiar shape of coronate leaflets.

4. *Dischidia (Conchophyllum) albiflorum*. Gr. Pl. CCCCX.
A. Fig. 8.

Habitus et foliatio Dischideæ, Collibus foliisque præsertim subtus punctis albis, folii paginæ inferioris perforatis. The larger most conchiform leaves are purple underneath.

Caulib. repentibus in arbor. ad articulos radicantibus.

Umbellæ lateraliter inter petiolares abbreviatæ apice clavatæ, trilobæ perennantes, bracteis minutis præditæ.

Floribus breviter pedicellatis, albis, tubo corollæ subglobose, fauce constricta, lamina oblonga, connivens, $\frac{1}{2}$ the length of the tube, intus carnosæ rugosa, fauce nuda nec villosa, nec annulata. Corona foliola omnium tenuissime, unguibus quite flat, laciniis planissimis simplicissimis, unguem superantibus apice dilatatis.

Anth. in conum connivent. membranaceum marginat. Cauliculæ clavatæ, longæ. Pollinia oblongia, æquantia glandula minima.

HAB. Malacca at Tabong and Verupha.

The species are difficult of discrimination, the distinguishing marks of this are its conchiform leaves, its white flowers, the rather elongated limb, the simple faux, and the simple foliola of the corona, which in all others have carinate or perhaps conduplicate lacineæ, whereas here they are plain, and in the shape of the pollinia; in this too they are longer than in the others, and their dilated toothed ends are curved outward.

Blume's *Leptostemma* can scarcely be adopted with propriety.

5. *Dischidia Rafflesiana*.

Foliosa ascidifera, longe scandens, ascidia grouped in large irregular often pendulous bunches, filled with ants, large irregular and variously angular on the surface, often falciiform; orifice transverse, narrow, lucid, otherwise yellow green.

Lamina inflexed simple, with a recurved margin, inside

black purple with numberless white dots, occupied by roots.

The internodes of the leafy portion elongated, leaves opposite, orbicular with a short cuspid, considerably concave margins and apex incurved, above angularly rugose, very fleshy coriaceous. Peduncles stout, perennial subclavate flowering part with an irregular surface generally much longer than the leaves.

Flowers not numerous on short pedicels erect, axis of the laciniae ochroleucous those of the sinuses of division are dark-green.

Cal. puberulous, pale ciliolate. Cor. urceolate, tube globose, laciniae connivent into an obtuse oblong cone: I have not seen the corolla open; after maturity the green colour disappears, the laciniae are merely teeth, not extended, throughout, cone very fleshy and tough, slightly bearded inside, sinuses obsoletely entrant, otherwise faux naked.

Coronal leaflets with short stout stalks, armed simply incurved deflexed expanded conduplicato-carinate.

Margins of fissures communicate, thick, subcartilaginous below slightly diverging.

Anthers oblong erect, terminal membrane long flaccid forming a white termination.

Pollinia very much flattened oblong somewhat curved, 3-4 times longer than the caudicula, which is dilated at the apex and prolonged beyond the base of pollinium. Style disc pyramidal, prolonged into a beak surmounted by a white head on a level with the summit of pollinia, it is articulated on the apex of the ovary and adheres firmly with staminal columns superficies below the angles of the stigmata.

Follicles pendulous, subsubulate rather stout flat and channelled, above are the seeds (the young only seen) comose at the apex.

HAB. Malacca not uncommon on trees and rocks at Pulo Bissar also on Puddam Battoo, mount Ophir alt. 2000 feet!

Spec. Char. Foliaceo ascidif. Ascidici in bundles separate from the leaves, oblong, variously angular, margin of orifice

inflexed into a large simple lamina, with recurved margin, leaves orbicular, concave, flowers urceolate, laciniae tooth-shaped, closely connivent. Coron. folioles dilated simply curved, conduplicate carinate. Pollinia oblong, flat, many times longer than the caudicula. Stigma rostrate, rostra cuspidate. Follicles flattened and channelled above, also known by the colour of their flowers. If not *D. Rafflesiana*, nominatur *D. viridescens*.

6. *Dischidia Rafflesiana*.

Scandens volubilis glabra, carnosa, ascidifere caulibus terebibus, ascidiis confertis oppositis brevissime pedicellatis ovatis, angulatis rugosis ad pedicellam apertis, collo substrangulato margine oris, inflexa in foramen laminæ linguæformis, intus atro-purpurea maculis minutissimis albis, radiculos ramosos in pedicellis axillisque ortas foveantibus, *fol. distant.* ! orbicularibus carnosius plus minus apiculatis marginibus subrecurvis, nervo medio promiculo. Racemis axillaribus abbreviatis, foliis brevibus pedunculo brevissime, crasso, minute bractiatis. Pedicellis filiformibus basi membranacea bracteatis pubescentibus, floribus inconspicuis luteo-viridibus.

Cal. 5-sepalus, sepalis ovatis, pubescentibus, submembranaceis, ciliatis. Cor. unceolata fauci subconstricta, limbo 5-partito, laciniis lanceolatis carnosius erectis conniventibus, intus apicem versus barbatis, *pilis simplicibus*.

Corona staminea 5-phylla foliolis lucidis stipitibus carnosius. 2-lobis, lobis membranaceis subconcavis *intus* productis: par quodque hippocrepidiforme, Sulcæ communicatæ valde prominentis.

Anth. ovatae, marginibus apicibusque membranaceis, Pollinia erecta oblonga compressa margine diaphana, caudiculis brunneis. Stigma apiculata.

HAB. Mergue. In arboribus indiscriminat. parasit. præsert. in vetustioribus partibusque mortuis.

Corona and Pollinia, see Pl. CCCLXXXVI. Fig. VI.

Florifera Kulwing, Dec. 1834.

Nec vera *Dischidia* ob coronæ foliolom difformi quamvis hinc generi proximum.

7. *Dischidia complex* Gr.

Volubilis locofoliorum, ascidiis magnis, oppositis, subreniformibus, compressis, gaudet.

These ascidia are very complete, presenting a rather small orifice near the petiole, the outer margin of this orifice being inflexed and formed into a second pitcher much smaller than the outer one, opening on each side by an oblique aperture, deeply lobed or furrowed on the upper carinate or lower side, a transverse section makes it very reniform.

The cavity of the outer pitcher crammed with radicles, the inner surfaces of both lurid purple with inconspicuous white spots.

Pedunculis longis, 3-uncialibus apice dilatatis, verisimiliter perennant. Flor. breviter pedicellatis subumbellatis albidis, (ante anthesin tantum visi). Cor. tubo subglobosa, faux vix coarctata, lamina æstivatione valvata, depresso-inflexa carinosa, brevia lata ovata.

Faux pilis subclausa.

Coronæ foliol. e plicata (simplicem,) cruribus longissimis angustis apice dilatatis transverse conniventibus vel recurvis.

Columna antherarum truncat. stigma vel styli apicem 5-gonum excedens.

Pollinia subobovata, caudiculis dilatatis. extrorsum duplicato-concavis, basin massular. quasi $\frac{1}{2}$ amplexant. margina interiore carinatis, et in mucrona ultra antheræ basin producta.

Pollinia appear furrowed along anterior faces.

Ovaria ?.

HAB. In arboribus Malacca.

A very distinct species, although in some others, there is a tendency to an inner pitcher.

Specific Char. *Dischidia complex*. Aphylla ascidiis subre-

niformis, compressis, lamina inflexa, in ascidia interius evolut. floribus alabast. apice depressis, fauce pilosa. Foliolis simplicibus. Polliniis antica sulcatis.

8. *Dischidia obovato*.

Scandens, caulibus teretibus, foliis breve petiolatis, obovatis, subacutis carnosis integerrimis, pallide luteo-viridescens. Pedunculis perennantibus more Hoyæ, intrapetiolaris cylindricis, crassitia pennæ corvinæ, floribus paucis inconspicuis albis. Cal. minimus, 5-sepalus, sepalis rotundatis, cor. urceolatis 5-dentatis, dentibus conniventes fere clausis, faux pilis clausa. Corona staminea simplex 5-phylla, foliolis carnosis albis, angular, basin bifidis. Anth. in conum obtusum conniventes-membrana marginatæ et terminatæ.

Pollinia 10 erecta, tumida obovata, et margine exterior dehiscent. linea diaphana nulla, tubo polliniorum tenuissima.

Stigma ovat. ad apicem angustatum obtusum.

HAB. Mergue. In arborib. *December*, 1834.

In a flower immersed in water, the dehiscence of the pollinia had taken place in situ, along the outer edge of each mass. The tubes emitted were short and very fine. See Pl. CCCLXXXVI. A. Fig. VII.

ASCLEPIAS.

Asclepias tenuissima? Roxb.

Glab. caulibus volubilis, foliis carnosis ovatis basi cordatis 3-nervis.

Paniculis cymosis, ramosissimus, intra petiolaribus; cymis subumbellatis, paucifloris, floribus minutas, purpurea, folliculis acuminis supra planiusculis.

Cor. notata 5-partita, tubo sub 0. Corona stam. 0. anth. membrana terminatæ, massæ polliniis transvers. affixæ, margo diaph. 0. Stigma planiuscul.

HAB. Mergue in humidis: *September*, 1834. Mergue Herb. No. 23.

MARSDENIA.

1. *Marsdenia* sp.

Longe scandens, caulibus viridibus. Fol. oblonga, ovato-obtusiuscula acuminata, basi cordata, venis secundariis distinctis apice bifidis et ope arcuat. convexis, vena intro-marginali obsolete, subtus valde pallida, sinus baseos paginæ corpusculifer. ciliæ interpetiolares nullæ, umbellæ interpetiolares, alternantis, petiolis æquanti densifloræ, flores majusculi, viridi lutescentes.

Sepala subcordata brevissima ciliata. Cor. campanulato tubo brevi suburceolato, limbo 5-partito, laciniis ovatis bases versus pilosis, ut etiam faux, æstivatio imbricata vix contorta.

Corona staminea 3-phylla processibus indivisis fere cordatis carnosogibbosis medio foveolatis. Antheræ obtusæ, margine rotundato membranaceo.

Pollinia erecta (geniculæ directione transversa) oblongo subangusto-obovata, introrsum curvata adeo ut apex utriusque in super glandulam quasi incumbit. Pl. CCCCLXXXV. A. Fig. X.

Stigma apiculo conico longiusculo ultra Antheras prominulo, apice emarginato.

HAB. Khasyah Mts. Scandens in aboribus in marginibus *Sylvæ Mumbre*: Nov. 11th, 1835. An *Marsdenia* sp.

2. *Marsdenia tinctoria*, Pl. CCCLXXXIX.

Suffrutex volubilis, succo vix lactescente, habitu ad minimum ordinis.

Ciliæ interpetiolares obsoletæ. Petiola apice pluri-glandulosa, venæ seconsariæ regulariter apicem arcuatum nexæ, confluentes.

Thyrsi, modus florentiæ insolitus subaxillares, ex umbellulis pluribus pedunculo dispositis oritur.

Inflorescentia centerpita.

Flores suave odorati, Heliotropaceo, parvi, ochroleuco-albi.

Cor. unceolati, faux pilis conniventibus clusa, tubus fasciculis pilorum 5, laciniis oppositis, ore flexis, medium versus stipatus, æstivatio imbricata.

Corona staminea 5-phylla, foliolis a medio infra carnosius filamentis adnatis, viridibus medio foveolatis, aspectu fere bicruribus, sursum liberis, linearibus, leviter canaliculatis, simplicibus, in antheris incumbens. Antheræ membrana ampl. repand. marginatæ et terminatæ.

Pollinia erecta, spathulato-obovata, compressa, alba, areolis utrinque sub 3-seriatim dispositis, marginibus simplicibus.

Glandula solita, caudiculæ longæ spathulatæ, valde viscosæ, pollinia huic infra apicem et facie antica affixa.

Stylus nullus. Stigma fere conicum muticum.

Ovula 4 seriatim, vix ultra 14, placentæ breviter productæ, et ovula lateralia semi-obtegentes.

Coronæ stamineæ coronæ Dæmiæ subaffinis, quamvis simplex. Pollinia difficult solubilia, ob caudiculas adhærentes: non torquuntur immersione! Granula pollinis in formationem! massarum intransientia præaliis pauca. Situs massarum albi insolitus, in aliis nempe caudiculam terminans.

Suddyah: August 16th, 1836.

TYLOPHORÆ.

Tylophora sp.—Pl. CCCLXXXVI.A. Fig. 1X. A memorandum of figures copied from Descaigne, Paris, *Feb.* 1832.

Hab. Etiam ad Mergue.

Fol. juniores oblongi carinati velutino-pubescentes apice depresso mammilla exserent.

Ciliis interputioli 0.

This is the *Bopple Sambing*, a virulent poison is produced from its seed.

If it be found to be distinct from *S. carinatus* it is to be called *S. virulentus*.

I am not certain about the stigmatic surface, for although the whole base of the style, indeed, all below the disc is papillose especially towards the ovaria, yet appearances suggest, that the tubes, will pass into the style tissue, not along outside until they reach the ovary, although from the articulation taking place on the apices of the ovaria; such a course would be anomalous. Emission of tubes in another seen, but no fecundation or penetration.

Sarcolobus, Pl. CCCCXV. Fig I.

1. Flower.
2. Corona staminea. Perianth removed.
3. Ditto, Anthers turned back. Pollinia in situ.
4. Pollen mass.
5. Long section of stigma.
6. Ditto, Partial shewing that it is *stigmatic* 0.
7. Ovule, of a bud about to expand, foramen visible with the apex of the secundine projecting beyond it.

Sarcolobus, Pl. CCCCXV. Fig II.

1. Corolla laid open attached to the caudiculæ.
2. Pollen masses with the tubes issuing from their ventral margin; gland fallen off.
3. Transverse section of the stigma towards its base, shewing the structure of an asclepiadeous stigma and that the pollen mass can only get access to the stigmatic tissue through the fissures in the column of stamens opposite the angles of stigma.
4. Ovule from a flower in which the pollen masses had fallen out and dehisced, but had not then entered the fissure. The apex of the nucleus is no longer visible.

Sarcolobi sp.

Caule, volubil. filiform. fol. subcarnosis lanceolato-subacutis marginibus revolutis, subtus purpureo notatis glabris floribus umbellatis, viridi-lutescentibus fusco-lineatis, umbellis axillariibus, (alternis nec oppositis) paucifloris, foliis multo brevioribus. Pedicellis basi bracteatis, ciliis interpetiolaribus 0.

Cal. usque ad basin 5-partibus, laciniis 2 exterior minor. Cor. rotata, tubo brevissimo, limbo 5-partito laciniis ovulibus subreflexis, faux, denticulis 10 potius monticulis. Cor. staminea 0, antheræ membrana marginatæ et terminatæ. Pollinia

basibus affixa transversa in stigmata incumbentia, margine diaphano 0. geniculis longissimis ovarium ordinis.

1. Bud and natural size.
 1. Do. magnified, perianth removed.
 2. Anther detached.
 3. Gland.
 4. Pollen mass.
 5. Corona staminea etc., of a bud at $\frac{1}{2}$ of its development.
 6. Gland of the same.
 7. Flower.
 8. Ditto vertical section.
 9. Ditto perianth removed.
 10. Ditto ditto anthers removed.
 11. Pollinia and gland.
 12. Long section of the ovarium and stigma.
- Vellore: August, 1833.*

CALOTROPIS.

Calotropis gigantea.

The only a normal form of this flower, is that in which there is an increased development of the processes of the corona staminea, with a corresponding increase in the anther and angles of the stigma. The greatest increase that I have seen is three, making 8 processes. In this case, between

three of those opposite the sepals, three smaller ones are developed opposite the petals. Opposed to these, three additional anthers are formed.

In the highest state of monstrosity, these additional processes are distinct, more frequently the anomalous adhere either entirely or partially to the normal ones. In the latter case, the base is distinct and opposite the petal. To such, there is not an additional distinct stamen, but the stamen corresponding to the normal process is increased in size; this depends on the degree of distinctness or cohesion of the accidental process. If this is considerably developed the anther is nearly doubled in size, I have never observed impregnation in these cases.

Calotropis gigantea, Pl. CCCXCVIII. Fig. II.

1. Corona staminea. Pollinia and glands in situ.
2. Ovarium etc., in which impregnation has taken place, the tubes are seen passing from the pollen mass and entering the style; there is a manifest enlargement of the ovary of the same side.
3. Pollen mass and tubes.
4. Portion of ditto as seen with Ross's triplet, here the external membrane does not appear divided into cells.
5. Tube separated.
6. Ovarium, the styles still adhere, but from the great comparative enlargement of the fecundated ovary, their junction is about opposite the centre of the larger ovary.

Calotropis gigantea, Development, Pl. CCCXCVIII. Fig. I.

First stage. Cor. shorter than the calyx.

1. Bud.
2. Long section of ditto.
3. Stamens in situ. no trace of corona staminea.

4. Stigma, the depressions on its angles visible but no rudiment of glands.

Second stage. Cor. $\frac{1}{2}$ longer than the calyx.

1' Bud.

- 2' Corona staminea and anthers: corona slightly developed, its processes are of a form totally different from that of the mature ones.

- 3' Stigma. Glands visible, arms not so.

Third stage. Cor. twice longer than calyx.

1'' Bud.

- 2'' Corona staminea and anthers, the fissure in the processes has closed up and the convoluted base is apparent, no traces of the 2 teeth at the upper part.

- 3'' Ovarium and stigma. Glands and arms developed but as yet unattached to the pollinia.

- 4'' Gland detached.

Calotropis gigantea, Pl. CCCXCVII. Fig. I.

1. Bud.

2. Flower, 3 times natural size.

3. Ditto Pollinia: adhering and detached.

4. Corona staminea.

5. Pollen mass with its gland. Front view.

6. Ditto lateral view.

7. Gland detached.

8. Long section of Pollen masses.

The same Pl. CCCXCVII. Fig. III.

1. Longitudinal section of the ovarium, the passage of the cord, down the base of the style is marked by a sphacelated appearance, at the upper end of the cavity the pollen tubes are seen, some of them are disarranged and their extremities seen.

2. Longt. section of the placenta, the pollen tubes are seen ramified over the placenta passing down its base.

3. Ovule, shewing the communication of the tube with the ovule at the base of the funiculus.

The same Pl. CCCXCVII. Fig. II.

1. Ovarium, style and stigma. Three pollen masses are seen with the cords running down applied to the style, only one ovarium is fecundated.
2. View of the base of the stigma, the cord is seen applied to the surface destitute of cuticle, which is always opposite to the space between the anthers.
- 3, 4, 5, Pollen tubes at different stages of growth.
- 6, 7. Ovula, with the tubes communicating with them.

OXYSTELMA.

Oxystelma esculentum Br.

Asclepias rosea. Roxb. Fl. Ind. 2 p. 40.

Herba scandens volubilis inter gramine in locis humidis proveniens, glabra caulis teres. Folio brevepetiolata linearia acuminata *subtus convexa*, 1-nervia, nervo medio infra prominula, basi subbiglanduso. Racemi intra petiolares foliis breviores paniculati erecto patentes, flores basi nudi? maximi diametro unciali inodori, extus albi, intus carnei purpureo reticulatim venosi, segmentis margine incurvis ciliatis.

Cal. 5-partitus laciniis lineari lanceolatis. Cor. rotata campanulata tubo sub o, laciniis 5-ovatis, basi latioribus patentibus erectis; corona staminea simplex 5-phylla, foliolis basi annulatis medio ventricosis, apicibus subulam acutam gynostegio longiorem et stigmatem in super incumbentem product. lateriusinque compressis et postice interiorive planis marginatisque. Antheræ membrana terminalæ. Pollinia pendula. Glandula brunnea caudiculæ breves: massæ pollinis apicibus affixæ spathulato-obovatæ compressæ margine interiori quoad antheræ loculos valde ventricosa vel magis convexam. anguli stigmatidis supra prominuli, caput vel superficies

supra peripheriam plana, centro convexo transverse sulcata vel sub-emarginata.

HAB. Bengal. In humidis vel secus rivos intra Pubua et Shirazgunge: Sept. 11th, 1835.

The annulus at the base of each process of the corona staminea may perhaps be considered as the rudiment of an outer series, although they are not mutually continuous in the spaces alternating with the processes. Its situation is in my opinion near Domia.

Oxystelma esculentum, Pl. CCCC. Fig. I.

1. Placenta, chief part of ovaria cut away, front view.
2. Ovarium partly cut away lateral section at least of the ovula removed, a few remain in situ. or attached by the boyaux.
3. Ovule viewed obliquely.
4. Ovule laterally.
5. Ovule obliquely.
6. Ditto lateral.
7. Front view.
8. Ditto ditto.
9. Ditto ditto.
10. All from the same placenta: 5 shews the termination of the boyaux.
10. Ovulum from a flower before expansion.
11. Ovaria some time after fecundation, lateral and longitudinal, the inflection of the septum remaining.
12. Central view of an ovule of do.
13. Ditto Dorsal.
14. The same under slight pressure.

The same Fig. II.

15. Dorsal view of ovule.
16. Central of do.
17. Longitudinal section through the greatest diameter,

shewing that the cavity is occupied by a cellular mass fixed to the *base* of the cavity.

18. Cellular body removed, from a young fruit an inch long.
Coma of the seeds, ovula 5 times longer than the ovula.

Oxystelma esculentum, Pl. CCCXCIX. Fig. I.

1. Coma 8 times longer than the seed, Raphal or inner face the young seed.
2. Ditto long section through broad diameter or parallel to the faces of the seed.
3. Embryonary sac of do.
4. Raphal face in a more advanced stage.
5. Ditto Longit. section.
6. Embryo detached.
- 7 Embryonary sac less advanced, but from the same placenta.
8. Embryo of do.
9. Seed nearly mature.
- 10 Embryonary sac detached.
11. Embryo.
12. Embryonary sac less advanced.

The same Fig. II.

1. Corona staminea etc., one leaflet removed.
2. Ditto all the leaflets removed. Two Pollen masses engaged in the clefts of fecundation.
3. Lateral view of Pollinia.
4. Ditto front.
5. Ditto back.
6. Corona staminea laid open, one leaflet and one anther removed, shewing the passage of the cord, the ovaries considerably enlarged.
7. Stigma, styles and apex of ovary, shewing the passage of the cords and the place of their entrance.
8. Pollen mass, dehiscent.

9. Ditto portion of, viewed internally.

10. Ends of two boyaux.

Fecundation in *Oxystelma esculentum* is by no means uncommon. The steps being almost precisely, the same as in *Asclepias*. Dehiscence of the pollinia never taking place in the cells, but in the clefts of fecundation, and occurring along the convex or inner edge, with regard to the anthers. The bundles of tubes passed to the base of the head of stigma, thence being reflected in passing down its prolongation: the base and the prolongation consisting of stigmatic tissue, the outer part being almost indurated into a sort of cutis, the tubes pass into the apex of the styles or at the point where the articulation takes place, and where the styles are green and have no lax stigmatic tissue. Thence downwards to the placenta, over which they spread, proceeding most distinct to the ovula, the groove of which they enter appear to penetrate into the substance of the ovulum to a little distance from the fundus of the groove.

They are in this state almost entirely empty. Extensive sphacelation of that portion of the styles, which are not stigmatic, and into which the tubes enter, takes place, but no signs of it are perceptible on the placenta.

The ovula at the period of the attachment of the tubes have undergone no change. The nucleary excavation is generally however more evident, and occasionally appears partially filled with dislocated tissue, no raphe is visible. The excavation in its more advanced stages appears to have a communication with the fundus of the foramen. At the period when the coma is equal to the ovulum, the cavity does not bear the same proportion to the ovule that it did previously. The raphe exists, shining along an elevated line and terminating towards the centre of the ovule. The central opaque portion of the ovule is solid, but no separation of the parts appears to have taken place.

At a somewhat later period the raphe is more developed,

and the central opaque portion is occupied by a cellular roundish mass which has the same direction as the nucleus, to the base, of whose cavity it is attached. This is the commencement of the embryonary sac.

The next stage when the coma was about 8 times longer than the ovule, presents no important change in the coat of the ovule, the embryonary sac is increased in size, and is now free from adhesion except by its apex to the apex of the cavity! This attachment is very slight, it contains towards its apex a globular semiopaque body, attached by a filament of similar appearance to the apex of the embryonary sac.

The next stage presents the young seed much increased. The embryonary sac much enlarged. The embryo attached by the apex of its radicle, by a very short thread which does not reach the apex of the sac, and the cotyledons considerably developed and alternate with the raphe, the traces of the original adhesions of the sac are visible.

The next presents the raphe completely developod, terminating towards the centre of the seed and towards the centre of the cotyledons.

The embryonary sac occupies the chief portion of the seed, and it is occupied chiefly by the embryo which has assumed its mature form the cotyledons, being now nearly opposite the raphe.

Finally the sac becomes attenuated to a membrane, appearing to contain no albumen, the embryo fills its cavity almost entirely and the cotyledons become opposed to the raphe.

The remarkable parts are in this, the incompleteness of the raphe, it has in common with some others as *Veronica*, the late appearance of the embryonary sac, its change of attachment, and the change in the situation of the cotyledons.

Bud $\frac{1}{2}$ line long, mass not separable from the cell, I see very little analogy between the formation of the pollen in *Asclepiadeæ* and the ordinary forms, in the earliest stage seen the mass consist of an excessively fine sac, containing much molecular matter, either scattered or aggregated in

transverse bands or forming merely opaque dots in both cases of irregular outline. In next stage the membrane is scarcely demonstrable, bursting under the slightest pressure, it is now filled with the granular matter, which is not however grouped but continuous.

In a flower-bud 2 lines long the mass has assumed its mature form, the outer membrane is cellular, and the granular matter divided into masses, corresponding to the cells, the inner membrane now appears to exist.

No other change takes place except in induration, and the more complete development of the inner membrane.

The best mode of accounting for this formation is to assume, that the original mass, forms directly the grains of pollen and that these never lose their original connection; or we may look upon the mass as consisting of a single original cell, which subsequently becomes indefinitely divided. To this view, the only objection is the persistence of the original cells, but this point is not yet sufficiently demonstrated.

CYNANCHUM.

Cynanchum inconspicuum, Gr. Pl. CCCCI.

Volubilis puberulum, foliis oblongo-ovatis acuminatis, basi profunde cordatis auriculis convergentibus supra velutino-lucidis subtus albidis.

Racemis umbelliformibus inter petiolaribus, pedunculo commune petioli subæquante, pedicellisque pubescentibus excedente, calycibus puberulis. Corolla patente-reflexa, laciniis oblongo-lanceolatis, intus lutescentibus extus albidis, glabris.

Ciliæ inter-petiolares nullæ glandulæ? aggregatia ad basin folii cujusque.

Corona stam. corolla 1 brevior, 10-fida, laciniis petalis oppositis minoribus erectis emarginatis intus carina sim-

plicei auctis, alternis horizontalliter conniventibus antheras insuper integriis.

Antheræ membrana cordata alba terminatæ.

Polliniæ ventricosa oblique oblonga latus interioris quoad antheras convexiora.

Caudiculæ breves lutiusculæ aspectu cellulosæ margo superus cum apice pollinia parallelus.

Glandula ovate, sulco dorso inconspicuo.

Stigmam muticum.

Ovula placentatioque ordinariis.

This species can scarcely be referred to any of Mr. Brown's sections, and it is intermediate evidently between his first and second.

It may be thus characterised:—

Sect. II. Corona staminea tubulosa, columnam includens, ore 10-fido, laciniis 5 exterioribus petalis oppositis intus carinatis.

C. inconspicuum mihi, foliis oblongo-ovatis acuminatis basi profunde cordatis; corona st. corolla brevior, laciniis 5 exterioribus erectis emarginatis, carneis simplicibus interioribus majoribus integris antheras insuper conniventes, interioribus integris os clausentibus.

1. Alabastrum.
2. Flower lateral view.
3. Ditto vertical, corolla out of perspective.
4. Corona staminea laid open, it is evascular.
5. Genitalia, cor. st. removed.
6. Ditto an anther removed shewing the direction of the pollinia.
7. Pollinia. Portion of an insects antennæ ? caught in the furrow of the gland.
8. Anterior view of Pollinia.
9. Posterior ditto.
10. Pistillum.
11. Ovulum.

Cynanchum viridiflorum, Pl. CCCCII. Fig. I.

9. Ovarium and stigma.
10. Ditto the pollinia in situ.
11. Transverse section of the ovarium.

Cynanchum ? Pl. CCCCII. Fig. II.

1. Flower viewed vertically.
2. Corona staminea.
3. Outer view of anther.
4. Inner ditto.
- 5, 6. Pollinia and glands.
7. Stigma and part of ovaria, Pollinia in situ.
8. Corona staminea. Anthers dehisced transversely. Pollinia in situ.

TOXOCARPUS.

Toxocarpus Roxburghii, Pl. CCCLXXXVI. Figs. IV. and V.

Scandens. Caulibus teretibus brunneis, fol. petiolatis oppositis obovato-lanceolatis, acuminatis integris, utrinque ad venas parce brunæo-pubescentibus infra reticulatis. Cymis inter petiolar. folio brevioribus, ramis divaricatissimis flexuosis, floribus citrinis subsuaviter odoratis. Pedunculis pubescentibus bracteis minutis ovatis. Cal. æqualiter et profunde, 5-partitus, laciniis eodem modo pubescentibus, ciliatis. Cor. infundibul. tubo terete, calyce duplo fere longiore, limbo 5-partito, laciniis linearibus subobtusis tubo paulo longioribus, reflexis ba-

sibus parce barbatis, linea 2 barbatis, basin paulo supra confluentibus.

Stylus clavatus annulo prominulo paulo supra basin bifido. Stigmata 2, simplici. Æstivatio leviter contorta.

Corona staminea 5-phylla, foliolis carnosis 3-lobis, lobo medio majore, intus dente antheræ incumbentibus aucto. Anth. apiculatæ longitudinaliter aliterque dehiscentes, annulo styli arcte adherentes.

Pollinia ovata quaternatim, corpusculo oblongo stigmatis singulo affixa cereaceo.

Stigma apice clavata longe producta, bifida, basin vix. 5-gonum. Glandulæ oblongæ ramosæ bifidæ. Ovarium ordinis. Genus distinctissimum inter Asclepiadeas veras et Periploceasque. Asclep. longistigma Roxb.

HAB. Ad littoram Mergue: *Sept.* 1834.

Toxocarpus, Pl. CCCCIV.

1. Plant.
2. Flower just before expansion.
3. Ditto expanded.
4. Corona staminea and stigma. Cal. cor. removed.
5. Ditto, Processes removed.
6. Process of corona staminea, outer view.
7. Ditto, inner.
8. Ditto, with anther attached.
9. Part of the column of stamens, Pollinia in situ.
10. Anther before dehiscence inner,
11. Ditto, Outer view.
12. 13. Pollinia and gland.
14. Style stigma and ovary, latter cut longitudinally.

A remarkable genus, forming the connecting link between true Asclepiadeæ and Periploceæ; most remarkable for the double number of Pollinia agreeing with the former in the nature of the Pollinia, these being waxy, but 20, resembling the latter in the gland, which is emarginate.

Asclepias longistigma. Roxb. Fl. Indica.

FINLAYSONIA.

Finlaysonia obovata, Pl. CCCCVII. Fig. I.

Volubitis. Scandens, caulibus teretibus, junioribus presertim purpurascens foliis obovatis abrupte acutis mucronatis integerrimis glabris *carnosis supra pilosis* subtus pallidis et pulchre reticulatis, junioribus, cymis inter petiolaribus foliis brevioribus ascendentis dichotomis pubescentibus, bracteis minutis, floribus parvis, cor. lutescent purpureo tincta, barba alba.

Char. Gen. Cor. rotata laciniis intus barbata, faux coronata processibus subulatis; Antheras 5 oppositis. Stamina faucibus inserte, libera.

Antheræ, longit dehiscens. apicibus carnosus 3-angularibus. Stigma inflexis. Massæ Pollinis 20 granulosæ obovatæ 4 antherarum cuique loculo, lividæ, egranulis quaternatim cohærentibus formatis. Corpuscula stigmatis apicibus dilatata longissime, ab apicem hinc usque ad medium fissa. Glandula carnosus subrotunda. Stigma 5-gonum apice coarctata sub bifida excavationibus transversis, 5 cum angulis alternantibus!

Cellulæ fibrosæ antheræ adsunt: etiam numerosissimæ. Textura, cellulosa laxa (stigma verum).

Impregnation in Periplocea, Pl. CCCCVII Fig. 11,

1. Transverse section of column below the anthers.
The intervals between the anthers, by which a direct communication can take place with the base of the stigma ; the apex of the style is green and shining, particularly during the expansion of the flower, when it seems to be lubricated by mucus.

The convexities correspond to the filaments.

- c. The grooves by which access is gained to the stigma.

2. Longitudinal section,

The filament cut through.

- a. Space alternating with the filaments, opposite and im-

mediately beneath the glands, so that the pollinia by mere falling can get access to the stigmatic surface. *b*. The part which corresponds to the stigmatic surface, it is greener than the body of the stigma.

3. In this case fig. 3 the granules appear to be held together by something viscid, and are apparently not contained in a tube, this is applied to the foramen which is near the hilum, and which is indistinct. In the figure, it would appear as if the upper part of the ovulum were filled with these granules, the lower remaining empty: no nucleus was visible.
4. Grains of pollen, one of the component parts has burst and sent out 2 short boyaux.
5. Ovule some time after impregnation, ovarium the length of the calyx. The nucleus is distinct, the foramen is more remote from the hilum and sphacelated.
6. In this ovule a mass of dark grumous matter was applied to the foramen, but did not appear to pass into it, since it was easily detached. The first rudiments of the nucleus are visible, this is filled with granules similar to the mobile ones.

The foramen is indistinct even at a very early period; the ovula at this time appear to contain scarcely any granules. The hairs of the ovarium which are developed post anthesin are punctuated: they contain likewise plenty of green granules; but the punctuated appearance is independent of their presence, continuing after the granules have been squeezed out, they appear to be elevated above the common membrane.

8. In several instances, part of the base of the flower, and the furrows leading to the stigma, have been covered over with what appears to be a waxy secretion; it is of a whitest colour to the naked eye, the microscope demonstrates it to consist of an infinity of granules, held together by some denser medium, in all probability it is owing to a solution? of the pollen masses in

the viscous matter dissected by the furrows, see fig. 2. It slips likewise into the furrows along, which it seems to produce the sphacelated appearance: thus it likewise produces on the surfaces over which it is applied.

9. The tubes reach the ovula and become applied to the foramina in a firm manner. In the instance figured, three tubes have united into one, these together with the common one, particularly the latter close to its entrance, contain granules and what appear to be coagula. No change is visible in the ovule except a slight opacity towards the foramen. This opacity is not central. the granules do not appear to be mobile while in the tubes, when they have escaped into the water surrounding the object, they are very mobile. The motion consists chiefly of rotation on their axis, there is scarcely any locomotion. In the above, 3 tubes are not united into one as it appears from the drawing; the appearance is owing to another tube being doubled on itself beneath that proceeding to the ovula. The tubes do not appear to enter far, if at all into the ovulum.
10. Group of Pollen grains which have dehisced.

The conclusions that I deduce from the above imperfect observations are as follows :

1. That impregnation takes place (generally) by the emission of tubes which enter the base of the stigma, proceed down the style, and are ramified over the placenta.
2. That the emission takes place extra antheram, and at or about the grooves on which spaces alternate with the anthers and communicate directly with the base of the stigma.
3. That to aid this emission, these spaces are always filled with viscid mucus at the time of impregnation.
4. That the tubes do reach the ovula, and become applied to the foramina, which are situated close to the hi-

lum and which are invariably directed upwards, and in contact with the placental tissue.

5. That no nucleus is visible until the tubes have effected their ends, that a subcentral cavity appears some time after the tubes have become applied to the foramen, which cavity appears filled with granules of an analogous appearance with those of the boyaux.
6. That the agency of insects or of any foreign thing does not appear to be necessary, since a mere falling from the anther will be sufficient to lodge the pollinia in the desired place.
7. That sphacelation about the grooves is very general, but that it does not take place along the styles.

Addenda: That the discoid head of the stigma is very readily separable from the base, that the passage of tubes to the ovula does not appear to be essential, as in by far the greater number of cases I have not been able to trace them in the placenta, although a section of this demonstrates it to contain abundance of mobile granules, that these or analogous granules appear to abound in the ovula after impregnation that they do not move while in the tubes, but are very rotatory when freed from restraint.

Mergue: November 21st, 1834.

laciniis rotundatis æstivatione contortis. Stam. 5 fauce inserti omninoque obcludentia exserta, filam. brevia intus pilosis apicibus in processum album orbiculatum gibberemve ampliatis. Connect. pubescens discreta. Anth. sagittatæ, loculis superne tantum polliniferis stigmato arcte cohærentibus. Stylus filiformi-piloso pubescens. Stigma conicum viride. Cupula glandulosa profunde margine breviter 5-loba pubescensque ovar. omnino ambit. obtegitque. Ovaria apice pubescens. Pollen læve and angulare.

The affinities of this plant is on the limits of Apocynæ and bordering on Asclepiadæ, to which at first sight it is referable from the appearance of the male organs, judging from this genus, I take the processes of the corona staminea of Asclepiadæ to be processes of the filament. They are hence essentially pentandrous.

STROPHANTHUS.

Strophanthus pentaphyllus Gr.

Frutex robustus scandens, ramulis brunneo-purpurascens. cortice tenacei, succo sublactacent coagulabili.

Folia 2-2½ breve petiolata long. 3½ lat. petiolus 2½ 3, linealis subelliptica breviter et subobtusè cuspidata basi subito attenuata, juniora præsertim conduplicata, maturiora paucè undulata venis secundariis distinctis et distincti arcuatim nexis utrinque sed præsertim subtus, paginæ inferioris intervenia dendroideo-reticulata, venulis anastomosantibus minime prominulis.

Cilia ad basin petioli in utroque latere subulata stipulas rudimentarias omnino mentiente,

Inflorescentia terminatis e cymis dichotomis 2, floris conflata aperta foliorum circiter longitudine, ramis articulatis. Bractæ lanecolato-ovatæ membranacæ aspectu brunnescentes, 1 subtus ramulum quemque, 2 minores oppositæ ad medium pedicellorum *extimorum* (i. e. cymorum partiatum quorum ramulus alter semper ? abortiens). Pedicelli 3-4 lineales sepala colore bractearum e basi cordato-ovata acuminata, subcarinata.

Corolla ampla campanulaceo-infundibuliformis ; tubus sulcis tot quot sepala et his oppositis 8-9 linealis medium supra subito ampliatus albus, maculis striatutisve purpureis laciniæ e basi cordato-ovata acuminatissimis, caudis nempe 5-6 uncialibus canaliculatis tortis, color laciniarum saturate brunneo-sanguineus. Squamæ albæ, latæ ad medium bipartitæ laminas laciniarum subæquantes in tubum decurrentes usque ad partem constrictam, tubo intus albo-lineis purpureis 5 squamis alternantibus.

Stam. ad tubi constrictiorem exsert. squamis opposita : filamenta libera breviter $\frac{1}{2}$ linealia, puberula, gibbere obclavato puberulo e medio partis adnato vel carina obtusa deorsum majore.

Antheræ obtuse vel auriculatæ sagittatæ, medio-stigmati adhærentes. Caudæ 4-5 longiores conniventes, antheris 3-4 longior. loculorum media superiora tantum pollinifera.

Stylus clavatus bisulcatus rugosus stamina subæquans basi purpureis. Stigma demidium inferius viscosum annuliforme superioris apiculiforme ad basin bipartitum.

Ovarium album subrotundum apicem versus utrinque profunde subsulcatum, fere bilobum, biloculare glandulæ dentatæ, ciliiformes inter corollam et ovarium.

Placentæ revolutæ, pagina exteriori undique ovulis obsita.

Folliculi maximi divaricatissimi, immatur. succus aquosus subviscosus copiosus demum sublactescens cito coagulans ; semina utrinque sed præsertim apice cornosa.

Sp. Char. Strophanthus, scandens, foliis ellipticis breve cuspidatis carnosis, floribus amplis, caudis longissimis, corona e squamis 5, ad medium bipartitis, corolla infundibuliformi, folliculis maximis, divaricatissimis, obtusissimis.

HAB. Belookor Jungle, Malacca, flowers throughout the year.

The points of the flower buds are not much exerted before the calyx has reached nearly its mature size, they are at first whitish ; but become soon blackish purple, they are

twisted from right to left; after anthesis they become more red.

The glands round the ovarium represent the interpetiolar glands; if they have any disposition it is in pairs or sets between each sepal, but even this is not over apparent.

The tail of the filament has a central vascular fascicle, the continuation of that of the filament itself.

The scales are also vascular, and apparently derive the fascicles from the parts of the corolla to which they adhere. The exterior fascicles are the largest, and the others gradually diminish towards the centre which is very short.

This can scarcely be Loureiro's plant, as the corona is different, indeed it appears to differ from all in 5 leaved corona.

STRYCHNOS.

Strychnos nuxvomica. Pl. CCCCXI. Fig. II.

Flowers all bibracteolate, hence the cymes ought to be much more compound than they are: it differs a good deal from the usual form of Apocynææ, especially in its valvate corolla, and its stigma.

India contains several species: five of which I know.

Ovula as in Asclepiadææ, but the groove is indistinct, the penetration of the boyaux into these, I have seen very distinctly. Sphacelation only takes place at the apex of the style and stigmatic canal. The tubes are of considerable length, irregular, generally empty, and much choked with coagula.

The actual continuation of these tubes from the pollen to

the ovula is not easily shewn, but indirect proofs are very satisfactory: viz, the resemblance of the part attached to the ovula to the upper part or that proceeding from the grain: 2nd the non existence of any tubes in the stigmatic canal before the application of the pollen to the stigmatic surface.

The stigma in one instance was 3-lobed, and as the lobes were equal, I consider this indicating a tendency towards the formation of other carpellary leaves. Had they been unequal they might have otherwise been accounted for.

HAB. Bengala Paulo infra *Jumalpoore*: in arenosis. *September 15th*, 1835.

The ovula resemble much in form those of *Asclepiadææ* and (all?) *Apocynææ*, that is, they present, when half developed, no traces of distinct coats. They appear to be destitute of the groove first described by Dr. Brown, as existing in *Asclepiadææ* and most perhaps in all *Apocynææ*. The part corresponding with this groove is somewhat papillose and to its apex, the pollen, tube becomes applied. These tubes appear rather empty, I could not trace them down the style. In two cases I observed them applied to the ovula, and in one or two more passing over the placenta: I can state nothing as to

whether they penetrate the substance of the ovulum or not, but the adhesion is sufficiently firm. The first change that takes place in the ovula after their application, consists of the outer or peripheriate tissue becoming more distinct and cellular; and in the production of a linear sub-irregular opaque line in the centre of the ovulum and in the direction of its longest diameter. On submitting ovula in this state to pressure, the only means by which, owing to their extreme minuteness and softness, they can be analysed, they appear like vesicles filled with gelatinous fluid.

Cor. gamopetala, tubo brevi, rotata, laciniis vasculorum fasciculis 3-donatis, sinubus evasculosis.

Stam. 3-seriata, 5 extima tantum fertilia tubo apicem versus inserta, filam. filiforme per totam fere longitudinem corollæ, adnata evasculosa! serie interna petalis opposita. Antheram loco pili cellulosi breves directione varii, serie intima eglandulis 5, petalis, oppositis hypogynis, apice ciliatis.

Anth. biloculares basin versus affixæ, longitud. dehiscent.

Pollen.?

Ovarium 1-loculare. Stylus brevis crassus, apice bilobus, lobis cordatis. Stigmata leviter papillosa marginem loborum occupantia.

Placentæ 2 parietales, cum margine loborum styli continui vel oppositi. Ovula plura bi-triseriata *antitropa*, (foramen hilum prope), tegumentes cum nucleo concretis.

OBS. The only objection existing against *Parnassia* belonging to this group, exists in its polypetalous corolla, and albuminous seed. In the latter not much stress is to be laid, as the albumen is scanty.

To the former in my opinion little value is to be attached, as there is an evident tendency in *Villarsia* to become polypetalous, as indicated by the short tube, and the evascularity of the sinuses, more stress should not be laid on its being a

polypetalous form in a monopetalous order, than its being a non-adherent form in a usually adherent order.

The fact of the opposition of the lobes of the stigma in *Parnassia*, although of less value, still is deserving of more consideration. It depends entirely on the assumption of the stigma being the denuded apex of the midrib. I say an assumption, because the idea seems to me totally wanting in some instances.

Long ago the observation of a monstrous variety of *Melilotus* rendered it evident to me, that the stigmata form in no case a single organ, if carpellary leaves are continuations of the placentary margins.* The proof derived from a monstrosity is however unnecessary, for instances are not wanting, in which there are two stigmata obviously continuous with or opposite to the placental margins, some species of *Phyllanthus*, *Nymphæa*, and all filiform stigmata longitudinally sulcate, shew this fact to demonstration.

It follows therefore that all stigmata, at least the distinct portions, are opposed to the placentæ. The question then arises, from what cause does their opposition as a whole originate. This is easily answered, parts of a vegetable may cohere either with contiguous parts of the same organ, or with contiguous portions of two different though similar organs. Let us take *Parnassia* for instance, we have 4 stigmata, and 4 placentæ, hence the number of stigmata is 8. If the union of these take place in such a manner, that the two stigmata of one carpellary leaf cohere mutually, then the stigma will probably appear to be a termination of the midrib. But if two stigmata of two contiguous carpellary leaves combine, we shall obviously have one opposed to the placenta. And that such is the case there can be no doubt; the fact of the almost universal communication between the stigma and placenta cannot be explained by the old theory; neither need we have recourse to the destruction

* *Notulæ*, Part I., p. 128.

of a portion of cellular tissue, nor the formation of a fresh tissue. As the placental tissue is the most lax part of the carpellum so are the stigmata.

No objection can be raised to the idea of union given above, it is not of uncommon occurrence in most parts of the flower, it is of very common occurrence in fruit, and latterly I have shewn it to exist in anthers; Mr. Lindley alludes to this union as giving one explanation of the structure of *Cruciferae*, and it is the most probable one. I may here observe that in perhaps all cases very great assistance is obtainable in anomalous instances of union, particularly between stamina or styles by taking into consideration the number of vascular fascicles. Thus the composition of the stamina of *Eriodendron anfractus* is at once pointed out by the number of vascular fascicles. It is of still more universal application to styles, the number of fascicles either corresponding directly to the number of carpella, they being in this single, or if there be more than one to each carpella, they are grouped according to their respective carpella, I am not aware of a single instance tending to diminish the value of this test. It is of difficult application in some instances, but the days are past for the minuteness of a flower being an excuse for not accurately ascertaining its structure.

If a floating *Parnassia* be ever found, it will probably be found to have evalvular capsules, because this is the case with *Villarsia*.

I therefore propose the order of *Villarsiaceae*, which will include *Menyanthes*, *Villarsia*, and *Parnassia*.

Cal. 5-sepalus æstivatione imbricatus, persistens. Cor. gamopetala, in *Parnassia* polypetala. Æstivatio imbricata, laciniis cristatis vel barbatis, raro nudis.

Stam. fertilia 5, sepalis opposita, in polypetalis hypogyna.

Stam. sterilia 5, vel 10, serie intime hypogyna, exteriore petalis opposita.

Ovarium liberum, 1-loculare. Placentæ parietal. 2-3-4.

Ovula plura.

Capsula (in aquaticis evalvis) bi-quadrivalvis loculicida, polysperma.

Cal. basi bracteolis 2-linearib. 5-sepalis, sepalis valde inæqualib., 2 exterior maximis ovatis, 2 interior minimis linearib. 5 *intermedio* lanceolato.

Cor. campanulata 5-partita, laciniis suberectis emarginatis. Stam. 4 didynama. Anth. cineræ. Stylus filiformis. Stigma capitata viridia. Sp. distinctissima.

HAB. In limosis paludibusque circa Mergue: no. 284. Sept. 1834.

CARDIOLOPHUS.

Cardiophorus decussata, Pl. CCCCXVII. Fig. 1.

Herba erecta, vel decumbens contusa sub aromatica graveolens, ramosa, 6-uncialis, caules 4 goni, fol. linearia denticulata decussata, flores axillares solitarii sessilis basi bibracteolata, albo limbo purpurascente.

Cal. 5 sepalus, quam maxime inæqualis, sepalo postico cordato; "2 lateralibus minimis obtectis."

Cor. tubulosa, infundibuliforme, limbo 5 fido subæquali.

Stam. 4 vix didynama inclusa, antheræ didymæ.

Ovarium 1-loculare placentis 2 crassis carnosis parietalibus stipitatis, stylus brevis stigma capitatum subilob.

Capsula (immatura) membranacea, bivalvis (valvis 2-partitis?) subglobosa, valvis medio septiferis, placentis adnatis, hæmisphæricis.

Semina 00. minuta oblonga angulata.

Obs. The largest sepal is invariably posticous, but there does not appear to be any fixed site for the demidiate, lateral one.

The situation of the placenta differs from that of most (all?) Scrophularinæ, but it is merely a difference of degree and evidently dependent upon the non junction of the placentæ along with the mesian line.

HAB. Bengal near Jubbulpore, Sept. 1835.

BONNAYA.

OBS. Cal. subæqualia 5-partit. laciniis linearibus. Cor. ringens, labio superiore emarginato, inferiore 3-lobo, intus bi-cristato (cristis medium versus liberis). Stam. 2, Stigma bilabiat. Glandula hypogyna concava inter corollam ovariumque, lab. inferiore opposita. Capsula cylindrica, vel subulata, biloculare. Semina 00. reticulata linea longitudinali 1 sulcata.

The two crests, from their situation, represent two abortive stamina, as they are placed one on either side of the middle lobe of the lower lip, (which is the situation of the lower pair in all didynamous species of this order) the 5th generally wanting, would alternate with the segments of the upper lip.

1. *Bonnayæ* sp.

Caulibus simplicibus ramosisve quadrangularibus, foliis oppositis elliptico linearibus, basibus subamplexicaulibus acutis, acutissime serratis.

Floribus racemosis albis, lab. inferiore maculis rosaceis.

Cal. 5-partibus, sepalis subulatis $\frac{3}{4}$ æqualib.

Cor. $\frac{3}{4}$ bilabiata ringens, tubo deorsum curvato labio super oblongo emarginato, inferior 3-lobo, lobo medio cordato, intus bicristato, cristis medium versus liberis factis, apicibus obtusis incurvatis, (rudim. stam?)

Stam 2 intra sinus labiorum inserta inclusa, flam. brevia. Anth. bilocul. loculo superior transverso, infero perpendicularia.

Stylus inclusus, filifor. Stigma bilabiat. Glandula hypogyna concava, subdentata, sepalo inferiore opposita, intra corollam ovariumque sita.

Ovarium bilocul. loculis pluri-ovulat. Pericarp. filiforme seorsum curvat. bilocular polysperma. Semina ascendent.

TREISTERIA. Gen. nov.

1. *Treisteria cordata* Gr.

Herbacea, decumbens, radicans, pubescens; caulibus 4-gonis. Foliis oppositis inæqualibus cordato-ovatis petiolis attenuatis, serratis.

Racemis axillaribus paucifloris abbreviatis, fol. breviorib. bractea setacea ad basin cujusque pedicelli; floribus inconspicuis, lab. super. brunneo-purpurascens, infer. albidum marginibus purpureis, lobo medio basin versus pilosa macula lutea, like a bat flying.

Cal. persistens, gamo-sepalus, 3-alatus 3-dentato sepalo antico 2-dentato e 2 coalitis formato?

Cor. bilabiat. tubo calycem excedenti, fauce subampliato,

lab. superior integro ciliato, ascendente, deflexo, 3-lobo, lobo medio majore.

Stam. didynama fauci inserta, filam. pars infer. arcuata ascendentia ad exertionem processum rectum nec ascendens filiform. pallide purpur. apice glanduloso luteo gerente.

Anth. loculi divaricat. apicibus barbatuli paris longioris cohærentis.

Stylus filiformis. Stigma inclusa bilabiat. Glandula hypogyna hinc fissâ (postice?) ovarii basi cingens. Ovar. calyce connivent. subinflato-inclusum, 2-locul. placentis carnosâ intra loculos productis, ovulis 00, curvatis, foramen hilum prope.

Capsula membranacea 2-locula, 2-valvis, dissepimentis placentis axique liberis factis. Sem. angulata plurima abortientia areolata compressione, Fig. 4. Pl. CCCCLVIII. ovule at a very early period. The same post impregnat. and Capsulæ parietes e cellulis transversis angustis creberrimis format.

HAB. Mergue. In humidis ripis. Ins. *Kully Gewen*; no. 561. Oct. 1834.

Obs. Apparently 3 sepals, but in reality 4, the posticous one wanting and the anticous formed of 2, as indicated by its 2-dentate apex. It has a central vascular fascicle, but which is very small in comparison with the two lateral ones, nor does it, like these last, send off any branches. The nerves of the lateral sepals are large, the lobe has likewise a central vascular fascicle which does anastomose with the two lateral ones, but only at the apex, the ciliæ of the upper lip are sometimes simple, at least before expansion. In all I have examined after impregnation, these hairs are beautifully and most minutely reticulated, the cells forming the reticulations running longitudinally.

Pentsteriæ valde affinis.

2. *Treisteria lanceolata* Gr.

Basi suffruticosa ; caulibus pubescenti-hirsutis, teretib. ; fol. petiolatis, lanceolatis, subrepando-crenatis, subacutis, subtus albidis, sublente cellulosus et ad nervos pubescent.

Racemo terminate, simplice nutante glanduloso piloso ; floribus breve pedicellatis, pedicellis glanduloso-pilosis, bractea linear-setacea glanduloso-pilosis paulo brevior, ex purpureo albi, 1 uncialis faciei Herpestis ; flores ante anthesin ascendent.

Pedicilli subflore bibractiolati, bracteolis angustiss.

Cal 5-phyllus, sepalis angustissimis, postico saltem per æstivat. longiore, florem super æquans, intermedium brevior, 2 antica florem paulo brevior omnibus glandulo pilosis.

Cor. infundibulif. tubo medio infra ampliato ; limbo 5-lobo subbilabiato. lobis 2 posticis albis.

Stam. 4, didyma, ad apicem partes tubo angustato inserto, inclusa glanduloso piloso filiform. Anth. bilocul. loculis parallelis, divaricatis parce glanduloso-pilosis, apices versus dehiscent. Pollen oblongum læve.

Stylus filiform. Corolla tubum subæquans. Stigma bifidum. Cupula hypogyna breviss. ovarium basin cingens. Ovar. basin solidum, 2-loculare, 00-ovulat. Ovulis transversis, placentis linear affixis, 2 seriatis, foramen hilum prope. Pl. CCCCLVIII. Fig. 6.

Suddyah Upper Assam : Aug. 22d, 1836.

Remarks. *Torenia Asiaticæ proxima est Torenia mollis edentata molliter hirsuta, magis erecta. Calycibus hirtis. Corollam calyce paullo interdum fere duplo longiore, pallidissime cærulea, lobis lateralibus partem saturatissime azureis, lobo medio labiis inferioris macula lutea. Filamenta longiora basin edentata !*

Ovarium apice obliquum. Glanduli cyathiformes. Stigma par brevius staminum tantum æquans.

Flores terminales, (pseudo axillares) fasciculati, vel interdum racemosi. Corollæ limbus interdum cæruleis.

Torenia edentula ; erectiuscula molliter hirsuta : foliis petiolatis cordato-ovatis, rugosulis, floribus terminalibus fasci-

culatis racemosisque corolla calycem vix duplo excedente, filamentis longioribus basin edentulis !

Proxim. *T. asiaticæ*, a quo distincta mollit. filamentisque omnibus simplicibus huic caractere a genere toto recedit.

In his omnibus testa foveolis exsculpta est, foveolis paucissimis in novo meo genere, plurimis in *Bonnaya* bracteata.

Testa (tegument) quam maxime coriaceum, albuminum firme adhærent. Tecta est pellicula vel cuticula tenuissima membranacea e cellulosa, quæ in seminibus siccis contrahitur in fundum alveolor. et his aspectus cellulosus sat, in hanc factis amplificatur et bullum format. foveolum quemque in super; ex hoc oritur aspectus papillosus seminum humefactorum. Hanc structuram observavim in *Vandellia*, *Torenia*, *Bonnaya* et in novo genere.

Pellicula testa est, *testa Vandellia* scabra *Bonnaya* brachiata in quibus et presertim priore reticulata est cellulosa et laxa, in utrisque.

Raphe e cellulis elongatiusculis formata præcursa est. In *Bonnaya* brachiata membranacea est, et hispidula pilis apice cruciatim fissis.

Mr. Benthon says, while refering to the distinctive marks between *Scrophularinæ* and *Primulacæ*, in allusion to the stamina of these two orders belonging to different series, that no trace of the inner series has as yet been observed in *Scrophularinæ*, except *perhaps in Bamia*. Without having any knowledge of *Bamia*, there can be no doubt that its disk is analogous to that of *Scrophularinæ*; and this again, although often incomplete, obviously represents either the *whole or portion of the* inner series of stamens.

HAB. Mergue. No. 45. *Augt* 1834.

Genus affine, Tittmanniæ sp. 1. differt, (181) calyce e carinata, et staminum pare longiore ultra corollam arctiato.

4. *Pentsteiræ racemosis* Gr.

Herbacea erecta pubescens, ramis divaricatis inferior subdecumbentibus cum caulibus 4-gonis, 4-alatis; foliis oppositis breviter petiolatis, ovatis, inferior in petioliam attenuatis, super basin cordatis, serratis cum mucronem, floribus axillaribus racemosisque luteis, racemis terminalibus, aliquando quaternatim subverticillatis.

Cal. 5-carinatus bilabiatum 2-partit. lab. super. dentib. 3 breviss. inferior 2-fido, sepalis linearibus acutis.

Cor. calyce paulo longior tubo deorsum curvato, infundibuliform ringens, lab. super emarginato, infer. 3-fido. Par. longius stamin. ad insertionem 1-dentat.

Antheræ perparia cohærentus paris superior breviorisque duplo majores. Connectivum pilosum, Rud. 5-0.

Stylus filifor. Stigma bilabiatum.

Capsula membranacea calyce connivente oblecta, fusi-formi-sub. 5-gona. 2-loculare loculo inferiore majore, dehiscentia valvaris. Placenta axisque libiræ factæ. Semina 00. muricata! Glandula hypogyna 0.

HAB. In arenosis humidis, Mergue, Bylou. 45. *Augt*. 1834.

VANDELLIA.

1. *Vandellia pedunculata*, Pl. CCCCXVIII. Fig. II.

Herba laxa decumbens, glabrata. Caules acute 4 goni soli subsessilia cordato ovata, obtusiuscula.

Pedicelli tetragoni ut *Torenia*, foliis longiores, axillares ante anthesin deflexis, ad anthesin et postea patentissimi

solitarii, oppositi; fructus valde elongatus uncialis vel $1\frac{1}{2}$ uncialis clavatus.

Flores mediocres, cæruleo-purpurei. Sepala 5 æqualia, linearia, demum paullo ampliata.

Cor. bilabiata ringens, tubo calyce longiore lab. superiore plano porrecto; emarginato, lab. inferiore 3-loba minuti crenulato, lobis lateralibus verticalibus: rotundatis, medio porrecto flavo basin macula lutescente.

Stam. didynama *inclusa* perparia arcte cohærentia. Filam. pavis superioris brevia, inferioris longa, extrorsum arcuata, basi paullo supra denticulo vel potius gibbere obtuso aucta.

Antherarum loculi contigui divaricatissimi. Connectivum loculorum stamina longiorum, et loculorum superiore paris brevioris mucronatum; paris brevioris loculorum inferiora in calcar productum. Pollen album, ovato, hinc sulcata glabrum. Glandula, hypogyna lutea postice incompleta, obsolete 3-crenatum et trisulcata, crenis lobis labii inferioris oppositis ideoque stamina sericei interioris parte. Stylus filiformis. Stigma par longius stamin non attingens bilamellat. lamellis patentibus intus papillosis.

Ovar. biloculare glabrum.

Ovula ordinis.

Capsula siliquosa, teretio subulata, sub semuncialis, calyce duplo excedens, bilocul. bivalvis, valvis integris margine planis, septis placentiferis, dein liberis, parallelis. Semina minutissima oblonga, albida foveolata; obsolete scabrella. Raphe linearis, inconspicue; chalaza punctiformis minima subclavata.

HAB. Upper Assam. In humidis *Suddyah*.

Distinct a *Vandellia* habitu, inflorescentia? labio corollæ superiore non fornicato, lobis lateralibus lab. inferioris verticalibus. Antherique loculis paris superioris calcaratis, an ideo segreganda.

Vandellia est corollæ *Toreniæ* anne non potius *Toreniis* ad jugenda.

1. Flower lateral view.
 2. Corolla vertical view.
 3. Do. upper staminiferous portion laid open between the labia.
 4. Pollen.
 5. Pistillum.
 6. Capsule dehiscent, valves incurved by dryness !
 7. Seed opaque.
 8. Do. immersed in water, viewed as a transparent object.
- Suddyah : Aug. 1836.*

2. *Vandellia scabra*, Pl. CCCCXVIII. Fig. IV. Benth. Scrophl. 36.

Annua, gracilis, basi decumbens, hirsuta. Caulis tetragoni. Fol. subsessilis inferiore ovata, obtuse, superiore ovato cordata vel rotundata, obsolete serrata. Pedicelli fasciculati graciles folia duplo excedentes filiformes ante anthesin curvatuli, postea cito geniculata a basi deflexa. Flores certe terminales, quamvis ob axillam unam ramum caulem continuantem emittente axillares videntur.

Calyx hirsutis, 5-partitus. Cor. mediocris, tubo calyce longior intus villosiusculo labio superiorum fornicato, obsoleti-emarginato irregulariter denticulato, venoso, fusco brunneo ; lab. infer. æqualiter 3-lobum deflexo-patens cæruleum, ad bases paris longioris aureo-velutinum. Dentis paris inferioris rotundatæ sessiles, rugosulæ, filamenta demum an semper erecta et exserta.

Connectivum submuticum, dorso apices prope denticulo celluloso aucta, antheræ pollenque albumen. Glandula postice incomplete.

Stigmatis lamellæ conniventes, antheras paris longioris attingentes.

Capsula globosa, sepalorum parum mutatorum subæquans, glaber. bilocularis, dehiscente generis, bivalvis, valvis cymbiformibus margine simplicibus. Septis his parallelis, placenti-eris, demum liberis.

Semina oblongo rotundata, obtuse angulata, plumbea, extus sub lente areolis albis conspicue reticulatis.

Raphe linearis, lævis, vix conspicua. Chalaza punctum apiculi atratum vix elevatum.

HAB. Upper Assam about *Suddyah*: *August*, 1836.

1. Seed opaque dry.

2. Do. opaque immersed in water.

3. Do. long section.

4. Transverse section.

5. Portion of cuticle shewing, that it is tranversed by the raphe, hence it is testa.

Suddyah: *Aug.* 1836.

OBS. In Vandelliis veris *lab. supertus corollæ certe fornicat., lobis labii inferioris deflexis*. Connectivum antheram loculorum obsolete mucronatum. Glandula eadem trisulcata eodem more opposita. Stigmatis lamellæ conniventes, parvis super antheras attingentes.

Connectivum etiam utrinque dente celluloso rugoso auctum.

TORENIA.

1. *Torenia asiatica*, Pl. CCCCXVIII. Fig. 1. Benth. Scrophl. Indica p. 38.

Basi repens glabrate, vel parce breviterque pilosa, folia cordato-ovata in petiolum attenuata, venæ secundariæ distinctiusculæ, apici arcuati confluenti, et nexæ.

Calyx subglabratus. Cor. calyce vix $\frac{1}{3}$ longior saturati-azurea, per pulchre, lobis omnibus rotundatis, tubo intus atrocæruleo striato, antheræ muticæ vel breve mucronatæ connectivo simpliceo, dentibus parvis longioris maximis, quasi *stipitalis*, atro purpureis.

Ovarium apicem versus antica gibbum, glandula completa cyathiformis.

HAB. Assam circa *Suddyam*.

1. Seed viewed opaquely.

2. Do. raphal face.

3. Do. Long section parallel to the raphe, hence the cotyledons are opposite this organ,
4. Seed immersed in water, viewed as a transparent object shewing that the testa does not dip down into the foveola which exists in the face of the albumen.

Suddyah: Aug. 1836.

2. *Torenia calcarata* Gr.

Cal. profunde 5-partitus. Cor. ringens, bilabiata lab. superiore emarginato fornicato, inferiore 3-lobo.

Stam. 4 didynama, inclusa, filamenta parvis inferioris, bases paulo supra processum dentatum gerentia. Anth. biloculares, divaricatæ diffformes, loculo inferiore parvis superioris calcarato. *Par inferium tantum adherens.*

Stigma bilamellatum. Discus hypogynus cupuliformis postice incompletus.

Ovarium biloculare, placent. central.

Capsula siliquæformis tereti-subulata ex maxima partem exserta, bilocularis, bivalvis, valvis revolutis, placentis liberis persistentibus, dissepimentum exmarginibus valvularum introflexis placentæ adnat.

Semina ovatim, areolis depressis rotundatis notata.

Herba caule radicante ramis floriferis erectis, obtuse 4-gonis.

Fol. anguste lanceolata, sessilia distanter crenata. Pedicelli filiformes axillares solitarii *alternantes*, foliis longiores, fructiferi patentissimi.

Toreniæ species discrepans loculo inferiore parvis superioris calcarato. *Bonnayæ* proximum, a quo differt tantum staminibus 4.

HAB. Bengal at *Jumal pore* in humidis. Sept. 23d, 1835.

Alternation and situation of parts, Pl. CCCCLVIII, Fig. 14.

BUCHNERA.

Buchneræ sp. Pl. CCCCXIX. Fig. 1.

Herba, spithamæa vel infra.

Caulis subtus terram squamis dentiformibus stipat.

Flores carnei, tubo viridescenti pubescenti apicem versus geniculato.

Capsula loculicida vel valve medio septifer. Placenta libera.

HAB. Burma *Isabagya* : May 10, 1837.

VERONICA.

1. *Veronica*, Pl. CCCCXIX. Fig. II.

Planta annua, spithamæa ramosa, ramis purpureis, inferior prostrato decumbentibus, fol. amplexicaulia opposita lineari-oblonga, grosse dentata, fusco-viridia. Racemi terminalis axillaresque erecti bractæ lineareis pedicellos æquantis, flores minute inconspicui cæruleo-albidi.

Cal. 4 sepala, sepalis ovatis perparia inæqualibus, 2 anticis majoribus, æstivatione.

Corolla, infundibuliformis calyce brevior profunde 4-partita laciniis sepalis alternantibus, irregularibus hoc nempe inter sepalis antica majora, æstivatione imbricata 2-lateralia exteriora, antico posticaque interioribus.

Stamina 2 epipetala, ima basin corollæ inserta, sepalis 2, posticis opposita, ideoque cum petalo postico alterna. Filamenta alba clavata, vel obsubulata, bases versus nempe attenuata, potius utrinque attenuata. Anth. basi affixæ didymæ, oculis infra divaricatis, ovatæ introrsæ albidæ, longitudinaliter dehiscentes. Pollen, leve, (*humidum tantum vide*) ovatum hinc sulcatum oblongum globosumve.

Ovarium subglobosum, hinc utrinque profundiuscule sulcatum, foliis carpellaribus nempe antico posticoque. Stylus obclavatus vel basin versus angustatus; stigmata 2 papillosa subcapitata, antica posticaque.

Torus hypogynus dilatatus circularis marginibus parum clavatis, ovarii basin amplexantibus ; ovarium biloculare. Placentæ 2 carnosæ septo, quod quoad axin transversum, adnatæ.

Ovula 00. antitropa, funiculus brevis, crassus, foramen ad hilum latus. Tegumentum simplex nucleus inclusus, canali cylindrico a basi fere ad apicem extendente.

Capsula calyce ampliato, subæquali foliaceo suffulta, compressa, utrinque profunde sulcata, stylo stigmatibusque brunneis apiculata, subcordata, utrinque compressa, dehiscentia loculicida, valvis demum bipartitum. Placenta demum libera, centralis. Semina (vix matura) ovalia compressa, leviter brunnea. Tegumentum exterius cellulosum albumini adnatum, albumen dense carnosum parcum.

Embryo minutus in axi albuminis locatis, orthotropus. Radicula teres obtuse, cotyledone planas? paullo excedens. Raphe linea prominula indicata ex hoc oritur faciem internam seminis angulatum esse ; cotyledones faciebus latioribus et venis seminis parallelæ. Plumula inconspicua? Chalaza punctum nigricans ad apicem rapheos elevatæ.

HAB. Assam. In sabulis humidis sublimosis, Diboro Mookh : *Feb.* 13th, 1836.

2. *Veronica*.

Herba spithamæa pedalisve erecta ramosa pubescente hispida ; fol. breviter petiolata cordato-ovata, crenato-dentata, obtuse, summis sessilibus. Racemi erecti, axillares, demum elongato foliaque superant. Pedicelli breviss. Bractea lineari-spathulata quemque fulciens.

Calyx profunde 4-partitus in lacininiis lineari-spathulatis piloso-hispidis ciliatisque, erectis, inæqualibus, 2 nempe majora, æqualia, 2 minora.

Stam. 2 e sinibus laciniaë corollæ posticæ utrinque exsertæ, inclusa.

Filam. filiformi. Anth. biloculares albidæ, loculis divaricatis.

Pollen albidum læve hinc sulcatum. Ovarium globosum fol. carpellaria secus dorsum medium longitudinaliter hispid. Stylus brevis. Stigma capitatum, papillosum.

Torus hypogynus annuliformis marginibus nempe parum elevatis, ovarii basin cingit.

Ovarium. biloculare ; ovula 00. transversa foramen hilum prope vix conspicuum.

Capsula cordata, bilocularis polysperma in loculicidia bivalvis, valvis demum bipartitis, membranaceis, calyce ampliato suffulto valvularum marginibus externis ciliatis, placenta adnata.

Semina 00. albida, transverse vel ascendencia, compressa, funiculo brevi affixa extus minute cellulosa, ovaria.

Raphe nulla saltem conspicue, chalaza puncta brunnea, medium seminis versus, cotyledone apices prope.

Testa subcoriacea, albumine copioso carnosio denso adnata. Tegumentum interius nullum? Embryo orthotropus axilis. Radicula teretiuscula hilum versus spectans. Cotyledones incumbentis faciebus latoribus, verisque obchalazam seminis alternantes. Plumula inconspicue.

HAB. Assam. In arvis, versus Gubroo-Purbut Jorhauth : *March 6th*, 1836.

Folia carpellaria antica posticaque, ideoque lacinus iisdem corollinis opposita. Situation and alternation of parts Pl. CCCCLVIII. Fig. 7.

CENTRANTHERA.

Centranthera hispida Br. *Digitalis stricta*, Roxb.

15. Partium situs et alternatio.

I believe the ovary to be dimerous, the fascicles of style being two, and nothing appearing to indicate the non development, two additional parts.

The æstivation of this order appears always the contrary to that of Labiataæ, the lower lip being external, and the middle lobe most external. There are no rudiments of

sterile stamina. The nucleus appears to cohere with the single tegument.

The direction of the flowers of *Peristrophe* before the twisting of the tube is, reasoning from analogy reversed : is the peduncle therefore twisted? I find in *Meyenia* and some others, that, if the situation of the inflorescence be such, that the upper labium be inferior or nearer the earth the peduncle becomes twisted. And this seems to be the cause of the twisting because in *Thunbergia grandiflora* when the situation of the upper lip is superior, as it sometime remains, no twisting takes place.

It would be worth while ascertaining whether the twisting might not be determined in all by deflexing the inflorescence so as to bring its point near the earth.

The presence of three bractæ to the flowers is constant? And points out the evident tendency to dichotomy that exists throughout the order, see N. ab. E. Of these the anticus one does not belong to the flower developed, for this being really terminal has no bracte but to the partial ramus of inflorescence, the lateral ones represent the situation of two lateral flowers not developed. That is in the present instance but if the flower be pedicelled then the lateral ones would correspond to two lateral pedicelli. In the former case the limits of the partial inflorescences are defined, in the latter they are not defined.

CYRTANDRACEÆ.

Thoughts on Cyrtandraceæ.

Definition of the order inflorescence etc. which in its dichotomy and bracteatation often approaches to that of Acan-

thaceæ. Remarks on the various organs, and appendages of the axis, the obliquity and inequality of the leaves, analogous to the same in Acanthaceæ. Affinities.

I believe Dr. Brown does not separate these plants from Gesneraceæ or Gesneriæ. The differences assigned by Lindley in his *Introd.* 2nd edition, are not defensible, since in my *Cyananthus* the ovary has a tendency to become inferior, neither is the absence of albumen constant.

From Scrophularinæ they may (when in flower) be distinguished at once? by the constant presence of 5 stamens in one form or another, whereas the 5th in Indian Scrophularinæ is as constantly absent. I have before observed that the bilocularity of the fruit of this last order is not constant. Is there no difference in the æstivation of the corolla.

On the whole, after Gesneriæ, they approach nearest to Acanthaceæ especially in habit and inflorescence. The gyrate form is very remarkable and was first pointed out by Brown in his *Aikinia*; every degree of irregularity occurs in the corolla from ringent to subregularity, the tendency towards the latter form is however rare. The calyx affords but few characters, my *Cyananthus* however is at once known by its petaloid pentangular valvate calyx.

The stamina are worthy of much attention, *Cheilosandra* having the anthers opening in a valvular manner, the valve being compound.

The hypogynous disk is less developed than in Scrophularinæ, neither has it a tendency towards assuming the form of an additional series of stamina, which it has in the order referred to.

The ovarium is constantly unilocular or of bilocular form, the placentæ do not cohere, it is therefore only bilocular by approximation, not cohesion of parts. *Cyananthus* is remarkable for its fungous placentæ.

The stigma affords generic characters the general form, is perhaps bilamellar which may be determined by the vascular fascicles of the style.

The habit is peculiar and is at once sufficient to distinguish them.

Verbenaceæ are not easily distinguished by characters except perhaps that of the placentation and the definite number of ovula. But of all these orders the æstivation should be carefully examined; the 5th stamen is absent in Verbenaceæ.

Is not my Chiliandra Wallich's Corisanthera?

Of this order India has many representatives, *Æschynanthus* and *Incarvillea* being the most numerous both genera averaging (several, say) 5 species each, 10.

Cyananthus,	1
Chirita,	1
Stauranthera,	1
Epithema.	1
Martynia?	1,	28

It may be considered to contain 35 or 40 species.†

They are generally hill plants delighting in wet very shady spots, few of the species are to be found above 4000 ft. The plains possess but few and even these have probably escaped from hills. Of the Indian species the most widely distributed are some of the epiphytical *Æschynanthi* or *Incarvilleæ*, and of these about 3 species are found on plains. *Martynia* has likewise an extensive distribution. The remaining appear to be local, especially the small one from Madamacan.

* Temporary names referring to undescribed genera in the collection of the author.

† Species referred to generally as examples.

Didymocropus oblonga, Pl. CCCCXL. Fig. III.

Didymocarpus aromatica, Pl. CCCCXL. Fig. IV.

Æschynanthus ramosissimus, Pl. CCCCXL. Fig. V.

Lysionotus ternifolius, Pl. CCCCXL. Fig. VI.

Structure of the leaves of Æschynanthus, Figs 1, 2, 3, 4.
Pl. CCCCXLI.

Both cuticles are very thick, the upper one particularly and are beautifully transparent, composed of angular cells placed at right angles with the axis. These cells become rounder and much shorter towards the surface.

The part of the leaf in which the green matter is deposited is exceedingly narrow and very opaque.

The primary vascular fascicle does not occupy the exact axis, but is nearest the inferior surface.

The inferior cuticle is composed of rounded and angular cells of large dimensions, both sections give at first the idea of pores existing in the surfaces of the cells. The cells contain a few green ovate or roundish corpuscles.

The intercellular spaces are extremely distinct and vary much in shape and dimensions. On examining with high powers the apparent pores, which are of large diameter and very distinct, one is induced to reject the idea of their being apertures.

1st. Because the appearance of a membrane covering them is sufficiently distinct, and like the remainder of the wall of the cell examined, green corpuscles are frequently seen adhering to them.

2. Because on varying the light, they do not assume the exact colour of the field in which they are viewed, but have the same appearance as the other cells.

3. Because I have seen torn portions of membrane adhering to their edges some of which then had every appearance of being open.

4. Because on looking at the attachments of the cells one with another, we find them exactly of the same shape

Clinta grandiflora, Pl. CCCCXL. Fig. VII.

Platystemma violoides, Pl. CCCCXL. Fig. VIII.

Stauragyne argentia, Pl. CCCCXL. Fig. I.

Aikinia brunonis, Pl. CCCCXL. Fig. II.

with these apparently pores, and in detaching the covering, and the cells one from another, we increase their number.

5. Analogy is against their being pores, no vegetable membrane having yet been demonstrated to be visibly porous.

Dissection proves them to be not pores, they are in fact merely impressions of attachments of the contiguous cells, see fig. 4.

The large size of the intercellular spaces is evidently adapted to the thickness of the cutis, and to allow of a free transmission of air, to the central green part. These spaces communicate directly with the stomata. This is scarcely to be demonstrated by transparent sections, but is by the opaque, in which we see the spaces filled with air reaching frequently to the outer layer of the cutis, in which stomata abound. It is a curious fact that no intercellular spaces exist, nor does a transverse section give any appearance of pores in the cells *between the midrib and outermost layer*. These cells are angular, much more so than those not immediately adjacent to the midrib. They contain few if any green corpuscles, see fig 1. The outer layer immediately opposite the midrib is destitute of stomata, the midrib does not appear to ramify, and is well supplied with spiral vessels arranged in a reniform manner.

The stem presents nothing peculiar, the cells of the pith abound in transparent granules.

The stomata are small as in most succulent plants.

Mergue: Nov. 7th, 1834.

viuscula interdum bibracteata, flore uno nempe abortivo.

Calyx profunde 5-partitus, laciniis imbricatis, lanceolato
linearibus persistentibus subinæqualibus, dense ferrugineo-
villosis apicibus subglabratis intus glabris carneis patentib.
post lapsu corollæ clausis.

Cor. bilabiata subrotata, tubo brevissimo labio utroque
patenti-reflexo superiore labio bifido, lobis rotundatis latis-
simis, utroque demum inferiore 3-lobo, lobis angustioribus
reflexo, præsertim supero, rotundatis, basi utrinque quasi fo-
veolatim, infero primo porrecto.

Stam. 4 fertilia, quinto rudimentario minimo dentiforme purpureo sanguineo subdidynama, par superus nempe brevius. Filamenta brevissima, cellulosa crassa, sursum curvata *i. e.* declinata, fere semel torta semi-tort. Antheræ basi affixæ, rotundatæ, connectivo lanceolato angusto, marginibus antheræ huic contiguis sanguineo-purpureis, antice glandulosæ uniloculares, valva semicompleta antice transversum dehiscentes tuncque bilabiatae.

Pollen pallide flavescens, glabram, anguste oblongum 3-sulcatum.

Glandula hypogyna cupulata lutescens integra ovarium basin cingit.

Stylus declinatus, glaber, subulatus, crassiusculus, albus, fasc. vasor. 2, distantes, centro canali stigmatico conspicuosculo perforato. Stigma simplex obtusum obliquum.

Ovar. glabrum ovato-rotundatum, 1-loculare foliis carpellaris anticis posticisque vix omnino superum, septis fere completis, in placentis binis extrorsum revolutis continuatis. Ovula 00, minuta placentarum facie exteriorum affixa, simplicia nempe tegmeni distinctæ nulla foramen potiusve situs intrantiæ boyau ad hilum prope.

Endothecum cellulæ conspic. fibrosæ, rotundatæ fibris simplicib. vel rarius divisis.

Æstivat. corollæ imbricat. lab. super lobis lateral labii inferioris partim overlapped, lobo medio lab. inferioris omnino externo.

OBS. Genus notis pluribus apte caractere præcipueque ob antheras anomalas, et prorsus insolitas. Initio bilocularis sunt, loculis bilocellatis, sitis etc. omnino normalis nempe e thecis 2 lateraliter (parallelis) stipita, (filamento) insertis. Posteriorum limites quasi loculorum obsolete fiunt, locellique minores et interiores quoad filament. firme cohærent. Limites horum locellorum a medio infra oblateralantur. Ex his oritur dehiscent. anomalis, valvula inferior semi-completa composita est e partibus superioribus locellorum inferiorum utriusque paris loculorum.

Margo dehiscentiæ idem est ac in antheris normalibus quævis per dimidian solitam longitudinem currit.

The great anomaly is the intimate cohesion of the two loculi, along the margin which in all others is distinct, and in the composition of the valve. This is the only instance of the kind I know, I refer to this formation in my short paper on Rhizophoræ, but was then unaware of the existence of an instance. All instances of the like dehiscences that is not lateral to the filament, arises probably from such cohesion, *i. e.* if there is no torsion of the filament. Lindley mentions its existence in a species of Diospyros, but does not state to what it is owing.

[Examine the situation of the anthers in the bud, as to what change arises from the twisting of the filament.]

Anth. alabast. ante filam. torsionem introrsæ, saltem quoad labia dehiscentiæ. The effect of the twisting seems to be to render the anthers more extrorse.

1. Corolla sometime before expansion.
2. Flower : shortly after expanding, seen laterally.
3. Do. sometime after expansion.

HAB. Mergue. This is also a common tree about Calcutta.

MILLINGTONIA.

Millingtonia simplicifolia, Pl. CCCCXLII,

In this plant we have an irregular pentasepalous calyx, the outer sepal being the smaller and very similar to the bractea, a tripetalous corolla, each squamiferous in the centre, two fertile stamina and a cleft disc. surrounding the ovary, this disk being deficient at the point alternating with the two fertile stamina. There is thus a high degree irregularly existing in the conformation of the flowers of this genus, the calyx being the only exception, at least so far as regards its component parts. The corolla is to be explained evidently by the coalition of four petals into two, and this is demonstrated by the size and obliquity of the single one and (to a certain degree) by its venation in the compound ones, the line corresponding to the line of union is vascular.

This at once reduces the situation of the stamina to their proper places, viz. opposite the sepals, and this is further corroborated by the evidently lateral situation of that which is attached to the single and smaller petal, and which is one-celled by abortion.

We have however still to explain the relative site of the

parts composing the disk; the teeth of which as particularly pointed out by the single one are opposite the sepals. This can only be explained by the supposition, that the intermediate series is either altogether wanting or represented by the tooth like appendages of the scales.

This is most likely the true nature of these bodies, it is at once evident that such appendages are opposite to the compound petals, and further there is but one developed opposite the smaller petal. Of the nature of the bifid scales attached to the back of the fertile filaments, I am at a loss; are they analogous to the tooth-like processes, in which case they would belong to the sterile filaments, with which however they do not separate.

Granting the above teeth to represent the intermediate series, the male organs are normally situated, and ought to be 15.

The ovary is two celled, the cells are anticus and posticus. The above view is quite distinct from that entertained by Wight and Arnott, to which a greater degree of objection exists in the fact, that their bifid petals are opposite the innermost sepals, while they have no analogy either of structure or situation with the three orbicular petals.

I am not sufficiently acquainted with other genera of the order, to form an opinion of the true nature of the appendages of fertile stamina.

The views of the authors of the *Prod. Fl. Pen. Ind. Orient.* were it not for the opposition of the fertile filaments to the interior sepals, would square well with the alternation of the teeth of the disk, the single petal is anticus.

1. Alabastrum just before expansion.

1a. Ditto.

2, 3. Flowers.

4. Inner view of compound petal and its scale.

4a. Same to shew the venation.

5. Ditto, simple petal, its one-celled scale and one tooth.

5a. Ditto ditto.

6. Stamen outer view of.

6a. Inner ditto. 6b. lateral.

7. Pollen, opaque.

7a. Viewed in water.

8. Ovarium and calyx.

8a. Ditto calyx removed.

9. Ovarium.

9a. Ditto longitud. section.

9b. Transverse.

10. Ovula with portion of the filament, the filaments probably are connected with fecundation.

11. Partium situs et alternatio, this must be so modified as to make the single petal anticus; the three forming this angle with the axis.

Obs. It is not improbable that the Malayan Millingtonæ are distinct from the India ones, at least from *M. simplicifolia*.

Dr. Jack's explanation of the structure of *M. Sumatrana* appears to me perfectly correct as regards the petals and stamens, the 3 large petals, being equilateral, equally veined; although rather unequal in size, and the two smaller being similarly central veined, and attached precisely to the bases of the fertile stamens, as the barren ones are to the larger petals.

With the Malayan plant, I only hesitate about the calyx, which I find to be 3-4 sepalled imbricately, the pedicels being 1, 2, bracteate, I see no difference in the venation of the sepals.

I would rest the distinction temporarily upon the fact of the aestivation of the large petals being nearly valvate, it is so along 2 of the 3 edges on the æquilaterality of the big petals, on the entireness of the smaller ones, or the want of auriculæ to the base of the barren anthers, and on the dehiscence of the anthers which is curious, and of the reflexed valve.

I have only examined imperfect specimens of the Malayan plant.

That any linear organ may have a mesial process, I think it is pointed out by the involucre of *Hibisc. surattensis*, in the earlier stages of which no trace exists of the subsequent well developed liguliform internal central process.

Which is in the calyx an analogous to what takes place in the corolla of certain *Bytneriaceæ* *Guazuma* etc.

This has the same simple development by points from a terminal discoid cellular mass.

The situation of the scale or appendage of either fertile filament is the reverse of that which takes place in the *Simarubaceæ* and *Zygophylleæ*, see *Lindley Introd. Nat. Orders*, p. 129, 133, hence if they represent portions of an additional series of stamina, in *Millingtonia* they would belong to the 1st, and in the two orders above cited to the third and fourth series, as in these two orders there is great probability that such is their present nature.

Granting their nature to be the same in *Millingtonia* and allowing the suppression of two petals, we shall have an attempt made at the development of four series of stamina, we must suppose the suppression of one intermediate series which should be opposite to the petals namely 4th. In this view the first series consists of two abortive stamina, the second of two abortive do. but more developed; the third of two fertile stamina opposite two sepals, 4th wanting; 5 opposite the sepals.

But this view does not explain the nature of the denticular scales, which seem to have escaped the notice of all authors who have written on this *group* or *genus*.

I am aware, that there is another mode of explaining the structure, which however does not take into account, the denticular bodies, to which from the fact, that it is single, attached to the smaller petal, I attach much importance by allowing the suppression of two petals, and the total suppression of the fourth series of stamina.

On the whole my view is liable to fewer exceptions, nor do I see any reason, why a filament should not become processiferous.

If they are stamina, then the 1st series is reduced to two, the 2nd is complete and represented by the denticular bodies, and the normal number hence will be 25, the third is complete, the 4th wanting, the 5th complete in number but not in function.

Racemo terminali paucifloro, floribus distantib. lilacino-cæruleis, lab. infer. macula lutea, macula lineis 5 cæruleis notata, lab. sup. basin versus lineis 4 cæruleis, sepalis æqualibus acutis, lab. super. emarginato, infer medio elevato subintegro, calcare conico subulato longit. labii inferior. Pedunculis fructiferis erectis.

HAB. In aquosis Kulweng. Mergue: *Aug.* 1834.

VERBENACEÆ.

Verbenaceæ Malayanae.

Cor. infundibuliform, æqualiter 4-partita.

Stam. 4 fauci angustati in annula inserta, vix exserta.

Stylus conicus stigma bifidum non exsertum.

CLERODENDRUM.

1. *Clerodendrum viscosum*.

Suffruticosa 4-pedalis, pubescenti-pilosa, foliis cordatis, acuminatis, distanter serratis serraturis mucronatis. Paniculis amplis terminalibus cymosis, dichotomis. Calycis sepalis, foliaceis, ovatis subæqualib. Cor. tubo calyce paulo brevior, pubescentia purpurea, limbo 5-partito laciniiis extus pubescent seorsum inclinatis. Stam. longissim. Anth. atro-purpurea.

Floribus suaviter odoratis.

In ruderatis Mergue: *Mergue Herb. no. 677. Nov. 1834.*
In iisdem lacinis Moulmein copiosa.

Ovarium typum Cyrthandraceum, evolutione sequitur carpella antica posticaque. Fig. 20, Pl. CCCCLVIII.

2. *Clerodendrum splendidum*.

Erectum basin suffruticosum caulibus 4-angularibus, profunde 4-sulcatis angulis rotundatis.

Fol. longissime petiolatis palmative 5-lobis, basi profunde cordatis, lobis acutis terminali maximo subcrenato repandis. Petiolis ad articulos tumidis. Pilis ciliatis inter petiolos.

Inflorescentia, terminalis cymoso-paniculata, cymis infernis foliis floralibus suffultis, superioris bracteis foliaceis petiolatis, spathulatis ovatis, petiolis nempe coccineis, ut tota fere inflorescentia. Cymis dichotomis, inferior longioribus adeoque inflorescentia pyramidalem fit. Pedunculis pedicellisque calycibus, corollarum tubis et genilatis coccineo aurantiaceis, limbo corollæ ochroleuco-carneum, fauce majis coccinea. Staminibus sæpius arcte deflexis interdum declinatis? Stylo deflexo.

Species pulche rima. Nomen aptum, quamvis characterem ejus nescio. Ut Tavoy circa crescit hanc plantam *C. splendidum* Wall. esse haud dubito.

HAB. In ruderatis circa Mergue, *July, August, 1834.*
Mergue Herb. 78.

3. *Clerodendrum densiflorum*.

Basi suffruticosa, erecta ramosa 4, 5 pedalis. Foliis longe petiolatis infernis cordatis acuminatis subintegris basi 3-nervus, nervo medio ad basin utrinque 1-glanduloso (glandulo e 4 confertis callosis composito) sublente utrinque punctulat. subtus ad nervos tenuissime velutinis.

Cymis axillaribus terminalibusque aggregatis corymbum densiflorem mentientibus, floribus albis. Cor. tubus rectus longissimus in laciniarum marginibus revolutis staminibus longiss. exsertis, stylum longe superant. Anth. cæruleo livide. Cal. glandulosis fructifer amplexus, ruber subcarnosusque.

Capsula atro-cærulea, baccata 4 sperma. Sem. nigrescentia angulato. Albumine 0. Radicula brevis infera.

HAB. Frequent Mergui in Ruderat. florem, *July to Nov.* *Mergue Herb.* 79.

4. *Clerodendrum affine*.

Frutex 8-10 pedalis, subsimplex, caulibus sub 4-gonis adpressa pubescent. Fol. cordatis acuminatis subintegris tactu mollibus. Paniculis terminalibus subpyramidatis thyrsoides bracteatis, bracteis foliaceis, lutescent, floribus parvis albis fauce rubescente laciniis subascendentibus. Stam. longissime. Anth. atro-purpureæ.

HAB. In aquis intra Kulweng et Mergue: *Dec.* 1834. C. viscoso valde affine. Typus formationes carpelli *Cyrthandræus*.

5. *Clerodendri* sp.

Cal. tubo subcylindræo, limbo erecto 5-dentato.

Cor. hypocraterif. tubo longo gracilis laciniæ æqualiter? patentis 5to majore et *profundiore* (æstivatione) extimo.

Stam. didynama longe exserta, æstiv. introflexa, (2 inferior longior.) Anth. oblongæ sinu affixæ, biloculi, longit. dehiscens.

Stylus filiformis exsertus. Stigma bifid. acutum (that is the style) is bifid, but the stigmatic surfaces are prolonged beyond them into 2 acute points, (Fig. IV. Pl. CCCCXLVIII.) stigma rather the biggest.

Stigmatic canal with long cells of exceeding fine tubes containing large granules, generally of the diameter of the tube.

Ovula 4 appensa. Ovar. 1-celled (the placentæ not united) in the axis, placentation as usual.

Fructus with as many lobes or furrows as pyrenæ basi calyce varie fisso cinctis baccatus 4 pyrenaceus. Pyrenæ formed by endocarp. 4-locularis. ?

Seeds 1, 4, often abortive appensed. Tegument cellulomembranous.

HAB. Malacca. Cotyledons, plano-convexiuscule radicle inferior.

6. *Clerodendri* sp. Pl. CCCCXLV.

Calyx 5-partitus amplus, demum carnosus ampliatus.

Cor. Unilabiata hypocraterif.

Stamina deorsum curvata longe exserta. Anth. sagittato-ovataë, bilocul. longit dehisc. Pollen purpurasc.

Stylus arcte sursum curvatus vel declinatissimus.

Stigmata 2, setacea.

Ov. 1-loculare. Placentis revolutis, biovulatis ovulis pendulis, appensis.

Fructus calyce ampliato cinctus.

Infloresc. dichotoma. Pedicelli clavati apicem infra articulati! Æstivatio discrepans from other Verbenaceæ, lobo dextro, (dorso spectans) lab. superior omnino interiore.

1. Alabast.

2. Expanded flower.

3. Corolla laid open.

4. Corolla before expansion, laciniaë cut away to shew the packing of the genitalia.

5. Anther back view.
6. Ditto front.
7. Ditto after dehiscence.
8. Back view of do.
9. Pollen in water.
10. Ditto after rupture which soon takes place.
11. Ovary transverse section of.
12. Ditto long section parallel to the carpella.
13. Pistillum, sepals cut away, style generally ascending.
14. Base of style.
15. Stigmata.
16. Placenta extracted with the ovule somewhat bent back to shew their insertion.
17. Pistillum after fecundation back of a carpellum laid open, shewing the situation of the ovula.
18. Ovulum before fecundation no distinction of coats.
19. Ovule after fecund, *a* testa and nucleus combined; *b*, embryonary sac globular above, in toto clavato, *c* hilum.
20. Ovule more advanced, *d* embryo. The embryonary sac is generally bilobed at the apex, here it is membranous but not so much as at its globular base, the bilobed apex does not become filled with cellular tissue.
- 21, 22. Embryonary sacs shewing the bilobed apex ! and membranous and membrano-cellular nature.
23. Ovary and base of style.
- 23*a*. ovulum of do. some time after expansion of the flower, excavation of the embryonary sac already commenced.

Obs. The situation of the flowers in *Volkameria* is certainly reversed, neither can I yet tell what is the cause of this. The 5th petal being certainly next the axis. That the fissure by which the corolla is rendered unilabiate is carried thro' the 2 petals corresponding to the upper lip of other plants of the Order is proved, 1st by the æstivation and 2nd by the situation of the stamina.

There is certainly some difference between the æstivation

of this Order, and of Labiatæ, one lobe of the upper lip of *Volkameria* being altogether interal.

It must be remembered that under *Vitex*, Brown says that *Hosta* is allied to *Vitex*, but that is totally different from *Cornutia* which is very nearly allied to *Ægiphila*, but both these genera are included in *Verbenaceæ* by Bartling and Lindley.

CALLICARPA.

Callicarpe lanata, R. Fl. Ind. 1, 391. Pl. CCCCXLVIII.
Fig. II.

The genus is allied in placentation to *Avicenia*, *Vitex*, and the involucrate genera. This placentation is remarkable and is analogous to that of *Cyrthandraceæ*, but differs in bearing definite ovula.

The pollen appears to have only one furrow.

Flowers purple, odoriferous.

Æstivation involuta et alternatam conduplicata connectione partibus cæteus glandulosus.

1. Alabastrum.
2. Flower, usually tetramerous.
3. Corolla laid open.

Stylus brevissimus, stigma bilobum, subcapitat.

Ovar. ferrugineo-pilosum, biloculare, loculis 2-ovulatis, ovulis pendulis ab apice placentæ, foramen ad apicem inferum.

HAB. In sylvis Mergue : Jan. 1835. No. 938.

Decadontia proximum, sed calyce bilabiato. Cor. hypocraterif. fauceque villosa, Staminiibus inclusis, antheris connectivo sub o, per totam longitud. dehiscent. Stylo sub o, valde distinct.

Placentæ intra ovulam nec product. Dixi ob filam. breviam, in Congeæ, Decadontiaque longe exserta.

PERONEMA.

Peronema canescens.

Arbor. Fol. oppositis impari-pinnatis, foliolis lanceolatis vel oblongo-lanceolatis caudato-acuminatis, integris concavis subtus albidis, alternis vel suboppositis. Petiolis supra planus utrinque conspicue alatus, alis occupying whole spaces between the leaves, not truly decurrent.

Panicula terminalis ampla, e cymis partialibus in corymbos secundaria disposit. pubescens, terminalis, Tectona formis.

Flores minuti albi.

Calyx tubus campanulatus. ad medium 5-partitus. laciniis patulis, demum immulatis, 2 infimis paullo majoribus.

Cor. extus pubescens tubo subinfundibulif. calyce parum longior, bilabiata, lacinia 4 superiores calycinæ subæquales, antico quinto longior duplo porrecto petaloideo.

Stam. 2, filam. robusta subulata æstivat. introflexa.

Anth. magnæ biloculares, reniformi-oblongæ, sinu affixa longitud. dehiscent.

The two lower ones are developed. Stam. superiora 2, ad rudim. filam. reducta.

Stylus filiformis basi et intus pilosus, stigma subsimplex subulata, subulo refracto.

Ovarium rotundato-cordatum, apicem dense pilosum, biloculare, loculis more solito biovulatis, ovula enclosed in partial cells from recurved placenta, ovula pendual.

Section of Ovary. Fig. III. Pl. CCCCXLVIII.

HAB. Malacca.

OBS. As the ovarium increases the calyx is forced to spread out, it is now pubescent, in all the exposed part marked by 4 lines converging to the cicatrix of the style and simulating well a Boragineous fruit. The placentæ have become fleshy, and the proper cells of the ovula, quite complete (except adhesion.)

This is evidently the *Peronema canescens* of Jack, who describes the ovary as 4-celled, and the ovules as erect, in which case a greater degree of affinity with *Teetona* would be manifested; he also describes the wing of the petiole as decurrent, *i. e.* derived from the leaflets.

The inflorescence and aspect of the young fruit, is exactly that of *Tectona*, so is the appearance of the under surface of the leaves, although these perhaps are not siliceous. It osculates directly between the *Vitex* section and *Tectona* do.

VITEX.

Vitex gamosepala.

Arbor. mediocris.

Fol. trifoliata, foliolis lanceolatis acuminatis venatio apocyneoid.

Cymis axillaribus foliis multo brevior.

Cal. tubo brevi bilabiato. labio super majore integro inferiore bipartito extus.

Cor. tubo anguste infundibulif. glandulosus calyce fere duplo longior. bilabiat., labio super. bifido erecto reflexo infer. 3-lobo, annulus pilorum ad medium tubi. Stam. 4 vix didynama, filam. subulatis robustis basi pubescent.

Stylus longitud. stamin., stigma bifidum subæqual.

Anth. biloculares narrow horse-shoe-shaped, filam. inserti in sinus. Cells not quite all along the inner margins of the curve, so that the anthers are mucronate at the base. See Fig. II. Pl. CCCCXLVIII.

Cor. extus glandulosa, in æstivat. the upper lip is outermost, lower lip middle lobe innermost.

HAB. Malacca at Ching Rhingull.

OBS. The upper lip of the calyx which is glandular outside, is made up of 3, it often presents faint obsolete traces of composition, sometimes decided. The venation is too irregular to decide the point.

In this respect it differs from *Vitex*, but not always unless indeed the anthers and stigma or fruit present corresponding differences.

GMELINA.

Gmelina arborea, Pl. CCCCXLIII.

Arbor mediocris ligno duro.

Flores ante folia evoluti. Inflorescentia vero dichotoma.

Ramuli sub 4-goni maculis albis.

Upper Burmah Nulloboom. March 27th, 1837.

2. *Gmelinæ* sp.

Frutex vel arbuscula, ramulis foliisque subtus cano-tomentosis.

Spinis divaricatis axillar. (pedunculis efformatis) armat.

Fol. oppos. suboppositisve. ovatis vel obovatis, subdistichis.

Paniculis racemiform, interd. racemi axillaribus tenuibus, folia subæquant.

Flores cernui majusculi lutei subsecundi. Bracteus foliaceus lanceolati-deciduus.

Cal. infundibuliformis, ore obseleti 4-dentato.

Cor. infundibul. bilabiata (ringens) tubo calyce duplo longiore, angusto, fauce ampliata, lamina 4-loba, lobis 3 subæqual. latis reflexis, 4 antica multo majore porrecto. Æstivation, the upper or central lobe of upper lip outermost, lower innermost.

Stam. 4 didynama fauce inserta, pari infero duplo major. Filam. deorsum curvatum, connectiv. carnos. horse-shoe-shaped. Cells linear occupying the border of the flat side, attachment in the sinus.

Stylus subulatus rather longer than the longer stamina, similarly curved. Stigma bifid. lacinia infera, duplo major.

Style articulated on the top of the ovary. Ovarium 4-loculare, placenta sepalisque cruciate, ovula pendula.

Ovarium ut videtur interdum biloculare, ovulis 1-cuique loculo, in this case all the cells are opposite and only one stigmatic lobe, and 1 vasc. fascicle to the style.

Fructus, basi calyce spathacea fisso, circumcinct. subrotundus, basi subobliquis luteis. Sarcocarp. crassum, baccatum; odore peculiar ingrati. Pyrena 1, ossea obovata, thick exceedingly hard, 4-locularis, loculis 2-3 effætis.

Sem. pendula tegument tenue brunneo, albumen 0. Cotyledones plano-convexæ, radícula infera brevissime.

HAB. In thickets, Malacca in flower all the year.

Cal. infundibulif. 4 dentato.

Cor. infundib. bilabiat. labio super, 3-lobo, (reflexo) infer integro porrecto.

Stam. 4, didynama, connectiv. hippocrepidif. Ovar. 4-locul. 4-ovulat. ovula pendulis. Stigma bifidum excavata. Drupe, pyrena 1-4 loculare, 1-3 sperma, loculis 2-3 effætis. Sem. pendula, exalbuminos,

It is of the same ovarial structure as *Tectona*.

Obs. I do not like the subdivisions of *Bartling* as given in

Lindley's Nat. Orders. Verbenæ is perhaps natural, but the involucrate genera, of which at least three genera exist, will form a very distinct section. Attention must be paid to the inflorescence which in many is truly dichotomous.

Gmelina cannot be associated with Vitex etc. on account of its unlobed fruit.

Augst. St. Hilaire is quite wrong in his assertion as to all except Avicennia having erect ovula. Brown on the contrary is quite right.

In this order the 5th stamen never? occurs in a rudimentary state, although it often does in its perfect state. This affords a diagnosis between it, add Bignoniaceæ, which otherwise might (*while in flower*) be confounded, that is, if the ovary be not examined. This is highly curious; because from the tendency towards dichotomy that exists one would have imagined that the 5th stamen would be more developed than any of the others.

In all Verbenaceæ the foramen is very indistinct, in the present genus even at a very early period and when the corolla about equals the calyx, there is no trace of any integuments, and just before expansion, it has the same appearance of a simple fleshy body.

SPHENODESMA.

1. *Sphenodesma pentandra*. Gr.

Frutex scandens, oblongo-lanceolatis acuminatis, supra lucidis glabris, 2½ inches long.

Floralibus pallidis subalbidis multo minoribus.

Capitulis axillaribus, pedunculatis, 6-bracteatis, bracteis involucris in modo dispositis lineari-spathulatis obtusis, albidis reticulatim venosis.

Flores 7 cuique capitulo, 6 ex axillaribus bracteari-involucrive, septimo centrali, terminali nudo.

Cal. subinfundibulif. submembranacea, ore 5-dentato, sinibus, denticulis totidem auctis extrorsum quasi plicatis.

Cor. calyce $\frac{1}{3}$ longior infundibulif. subregularis laciniis 5, patente reflexa fauce villosissima colore plumbeo-viridis, faucis barbæ azurei.

Stam. 5 exserta 2 exteriora (inferiore) paullo longiora. Filam. subulata alba.

Anth. ambitu subtrigonæ crescentiformi, medio versus affixam. Connect. carnos. cellulos. papillos., loculis divaricantibus *adnatis*. Stylus stamina subæquans, teretiuscule lilacinus glaber apice bifidus ramis oblique truncatis apice stigmatosis.

Ovarium dense hispidum pilis pallide ferrugineis 2-loculare.

Placenta centralis thickened ex hujus apicem discoideo-ovula 4 nucleariform pendula, an extrant angle on either side divides the ovula of each cell from each other, and as this reaches the wall of the cell, the ovary becomes in a sense, 4-locular.

HAB. Malacca: *June* 1842.

OBS. An elegant shrub hair of faux stupose and fragrance very pleasant, upper 2 lacinia of corol. are outermost, 5th innermost, that of calyx open.

Each branch of the style has its own canal.

It is more Verbenaceous in its pistillum than in any other part.

Considerable time elapses between the expansion of all the flowers, the central one is most precocious.

2. *Sphenodesma triflora*. Gr.

Ramuli ferrugineo-lepidoti.

Folia ovato-lanceolata quasi pendula, obtusa, glabra, coriariuscula integra, venis 2 durus paucissimis arcuatim nexis, interveniis inconspicue areolatis. Paniculis axillaribus et terminalibus, altogether ample, ramulis (ultimis) oppositis, 3-floris, flora centrali nudo præcociore, laterali 3-bracteatis, bracteis lineari-spathulatis, calycem excedent. centrali majore, inflorescentia grisea, fl. parvi sanguineo-purpur.

Calyx infundibuliform leviter 10-striatus griseus, 5-dentibus erectis.

Cor. infundib. tubo calycis longitudine, 5-partita laciniis reflexo-patent. subcordatis with a slight disposition to $\frac{2}{3}$ labiation, line of coloration abrupt along the faux.

Stam. 5 alternant. fauci inserta, filam. atropurpureis, subulatis erectis, 2 superior vel posticis paullo brevior, Anth. longe exsertæ oblongæ, basi bilobæ, sinu affixæ, biloculari, longit. dehiscentes.

Stylus albus staminibus $\frac{1}{3}$ longior declinatus. Stigma bifidum acutum. Annulus pilorum tenuis ad insertion. filamentor.

Ovarium oblongum glabrum apicem parce glandulosum biloculare, loculis 2-ovulatis, ovula pendula, divided from each other by a process of the placenta which reaches to the wall of the cell, where it is truncate. ovules reaching quite to the fundus.

Pollen ovato-oblongum glabrum, 1-3 plicatum. Ovary with the base surrounded inside by a series of erect calycine hairs.

Nothing can shew more clearly than these instances, that the ovarium in all is unilocular at the apex; the placenta, if its apex is alone considered, is really Santalaceous.

Although the involucre is generally small, yet the lower ones of some panicles here and there are as large as ordinarily happens, in all, the flowers are 3 only, and this is the only species in which there is no correspondence between the flowers and the involucrate leaves, those being to these in all others *equal plus one*.

The inflorescence in this species is freely cymose, the lateral flowers in each of the dichotomes being wanting, we may hence expect 1-flowered pluri-involucrate inflorescences.

Sphenodesma triflora. *Cymis trifloris*, floribus laterali tribracteatis.

Malayan name Aloor Gagah.

HAB. Malacca at Verupha.

HEMIGYMNIA.

Tectona has rotate quite regular *Cordia*, or *Ehretia*-like flowers. The stamina are quite equal, and regularly exerted. The anthers are likewise equal, although of a form admitting of divarication of the cells.

The calyx, looks *Verbenaceous* in *Campanula* and regular, rather deeply 5-6 partite. The style is subulate has 2 vessels, and each branch with two brachiate branches at the apex, each terminated by a punctiform papillose stigma. The ovary is glandular, (orange) at the base, it is really 4-celled, each cell has one anatropous ascending ovule (or sub-appended,) they appear to be nucleary, and are furnished with a very short raphe vessel.

The æstivation of the calyx is imbricate, so is that of the corolla, 2 lacineæ being outermost, and 1-innermost. See right hand Fig. VI. Pl. CCCCXLVIII.

The calyx becomes completely enlarged and depressed, and incurved apex inflated, and the ovarium becomes round completely spongy, presenting a St. George's Cross in the centre, the two larger arms being utrinque 1-vascular, and is consequently the placental or true septa, the others are 1-vasc., so that it only differs from the others in having the dorsal septæ very complete. See Fig. VI. Pl. CCCCXLVII.

The young seeds are completely appense.

From *Tectona*, *Hemigymnia* differs in the ribbed calyx which becomes cupuliform in fruit with a crenate or denticulate margin, and only appears to $\frac{1}{2}$ enclose the pericarp, the attenuated subulate apex of which projects long beyond it, it also differs in its infundibuliform corolla, contrasted with the rotate one of *Tectona*, though its calyx is infundibuliform, which is singular.

It also differs abundantly in its 4-partite style, with linear stigmata whereby it approaches nearer *Cordia* than *Tectona*.

I propose calling it from its half enclosed pericarp *Hemi-*

gymnia in contradistinction to the inclosed pericarp of *Tectona*.

The flowers at first sight are like those of *Pemphis*.

Calyx infundibuliformis, striatus, 5-dentatus. *Corollæ* tubus infundibuliformis; laciniaë 5 (angustæ, tubo duplo longiores.) *Stamina* 5 aqualia, inclusa. *Ovarium*, 4-loculare, 4 ovulatum: ovula solitaria, ascendencia. *Stylus* bifidus, rami profunde bipartiti, intus stigmatosi. *Fructus* (immaturus) drupaceus, rostrato-cuspidatus, calyce cupiliformi-semicinctus.

Arbor *mediocris*; partibus novellis pube ramosa tomentosis. Folia *opposita, cordata, vel cordato-rotundata*. Inflorescentia *terminalis, cymoso-corymbosa*. Flores *congesti, in apicibus pedicellorum brevium articulati, mediocres, albi?*

Habitus quodammodo *Rottleræ*, aspectus florum *Lythrarius*, *Pemphidis* si velis.

Hemigymnia *Macleodii*.*

Habitat: *Sylvæ Jubbulpore vicinæ*, plerumque cum *Tectona* consociata.

AVICENNIA.

The species of *Avicennia* appear to be in a very confused state in Botanical works.

Avicennia tomentosa.

Arbor. 20-30 pedalis. Ramis laxiusculis ramulorum internodiis incrassat.

Fol. oppositis exstipulatis breve petiolatis (petiolis basibus subconnatis, bases versus superne axillisque pilosis) lanceolatis utrinque attenuatis integris glaberrimis acutis, carnis subtilis albidis.

Spicis terminalibus paniculatis, oppositis, floribus basi 3-bracteatis. decussata oppositis, parvis inconspicuis luteis.

* Calcutta Journ. Nat. Hist. vol. iii. p. 363.

Calyx 5 sepalus, sepalis ovatis obtusis bases versus carnosus piloso-pubescentibusque æstivatione imbricatis.

Cor. gamopetala infundibulif. carnosa, tubo calycis longitudine, limbo 4-partito laciniis ovatis patentibus, apicibus subdentatis æstivatione imbricatis.

Stam. 4 fauci inserta laciniis corollin. alternant. Filam. subulata. Anth. didymæ longit. dehiscent. subexsertæ, loculis adnatis compressis. Pollen album ovatum læve hinc sulcatum.

Ovar. liberum cylindrico-oblongum, apicem versus pilosum, pilis albis cellulosus.

Stylus crassus breviss. Stigmata 2 simplice acuto conniventia, ovar. 1-loculare septis 2, stigmatibus alternant. incompletis. Ovula 4, pendula ab apice placentæ centralis libera, foramen infer. ad apicem ovuli.

HAB. Inter Rhizophoreus secus littoram Madamaca alibi que vulgata occurrit. *Mergue Herb.* 969.

An Verbenaceæ, cum placentæ ovulorum structura maxime accedit. fol. subtus lepidota, squamis sæpius 4 lobis, medio pilifer. Pilis articulatis articulis superior demum deciduus? nec vere tomentosa. Cor. extus pubescens.

Avicennia tomentosa, ovar. 2 loculare affinites placentæ cum *Congea* etc. maxima.

I met with three forms of this genus about Malacca, of which the following are the differential characters, and detailed descriptions drawn upon the spot.

2. *Avicennia resinifera* foliis lanceolatis acuminate glabris subtus albidis, corollæ lacinia postica integra, fauce subannulari, antheris inclusis, stigmata subincluso, fructibus apice cuspidato-attenuatis, rugosis, embryonis radícula infra apicem villosa-barbata.

A. resinifera Forster? Jack Mal. Misc. 2,58 sub *Pyrrhantho*. Arbor mediocris. Folia subtus vix reticulata. Flores parvi.

DESC. Arbor. ramulis articulatis.

Folia lanceolata acuminata subintigra, coriacea subtus albida, but without tomentum vix reticulata.

Spicæ axillares et terminales, ramosæ ferrugineo-velutinæ.

Flores parvi, several times smaller than in the other, oppositi inferiores distantiusculi superiores, conjesti, 3-bracteati.

Calyx 5-partitus læciniis oblongis.

Cor. subrotata, 4-partita extus velutina. Æstivatione fere valvata, thickened at the faux almost into an annulus.

Stam. fauci inserta. Filam. breve incurva. Anth. bilocular. introrsæ; cells as it were folded together, mucronulate.

Ovarium oblongum *pubescens*. Stylus brevissimis robutus. Stigma bifida vix ultra faucem exsertum.

Placenta etc ut in altero sed brevior, ovula viewed as opaque bodies, present white points.

Fruit with a surface like the under one of the leaves, transversely wrinkled, lanceolate, compressed, lengthened into a longish point at the apex, edges slightly furrowed, at the base of the calyx, but this is not forced to spread out as in the other, bivalvular.

Placenta at the base of the seed on one side.

Seed *conform*, without integuments, inner cotyledon projecting beyond the apex of the outer, both cotyledons are deeply bilobed, at the base.

Radicle long, inferor, just below the conical apex with a thick brush of hairs.

HAB. In limosis littoral Malacca.

This is the species to which Jack alludes sub *Pyrrhantho*, Mal. Misc. 2-p. 58.

Avicennia foliis lanceolatis acumianatis glabris subtus albidis, floribus (parvis) 4-partitis fauce subannulata. Antheris subinclusis fauci insertis. Stylo brevissimo, stigmata subinclus. Fructus apice attenuatus, rugosus. Radicula, infra apicem villosa-barbat.

Villi radice septuli.

Avicennia.

Cal. 5 partitus, imbricatus. Cor. regularis vel subregularis rotata (carnosa) lacinia postice integri vel emarginata.

Stam. 4, subæqualia sinubus vel faucibus inserta.

Ovar, 1-loculare, placenta centrali (4-gona) ovula 4, pendula ex apicem placentæ (inter angulos). Stigma bifidum.

Fructus, capsularis, bivalvis, 1-spermus. Semen albuminos. (tegumento 0.!) radícula villosa infera. Cotyledon complicat.

Arbores; ramulis articulatis foliis oppositis integris.

Flores spicati, oppositi, inconspicui certe ad oleum spectantes.

3. *Avicennia intermedia*, foliis obovatis, ovato-lanceolatis vel lanceolatis, acutiusculis subtus albidis reticulatis, floribus capitellatis, sepalis ciliatis, corolla lacinia postica sæpius integra. Staminibus subexsertis, stylo conico bipartito inclusa, fructibus amygdaloideis vix compressis, albo pubescentibus embryonis radiculae infra apicem villosa barbata.

Frutex. Flores mediocres.

I only met with this on Pulo Java close to Malacca, it is probably a hybrid between the two preceding species.

Desc. Frutex: 4-5 pedales ramulis 4-gonis. Folia obovata vel ovato lanceolata pallida integra coriacea subtus alba, quasi brevissime tomentosa. Exactly intermediate between *A. tomentosa* and *resinifera*.

Pedunculi axillares et terminatis, the axillary ones solitary in the last axils 4-goni simplices vel divisi.

Flores mediocres, incapituli pauciflori terminali dispositi with a tendency sometimes to become racemose, intermediate in size between the two other species, 3-bracteate. Sepal pulchre ciliatis. Cor. subrotata 4-partita, laciniis integris, postice paululum latior. Stam 4 faucibus inserta just below sinuses. Anth. basi affixæ subexsertæ, conduplicatæ. Stylus robustus brevis subulato conicus bipartitus laciniis approximatis glaber. Ovarium cylindraceum, pubescens placentata ut in aliis.

I have only seen this on Pulo Java, close to Malacca:

all the specimens were shrubby. It may possibly be a male between the two before described species.

Fruits very small amygdaloid compressed apiculate by the style, glaucous rugulose, at the base of the corolla and calyx, 1-valved coriaceous.

Outline of embryo or seed, cordate-ovate, inner cotyledon projecting a little beyond outer. Radicle barbate below, subtruncate.

Avicennia intermedia foliis obovatis. Frutex ramulis 4-gonis ovato-lanceolat. vel lanceolatis, acutiusculis subtus albidis reticulatis; floribus capitellatis (mediocribus) sepalis ciliatis. Cor. infundibulif. rotata, laciniiis subæqualibus, postice sæpius integra, æstivatione imbricata. Stam. subexsertis. Stylo coneco breve bipartito incluso. Fructus pario vix compresso, albo pubescento, radícula infra apicem villosa barbata.

4. *Avicennia obovata*, foliis obovatis, glabris subtus reticulatis, corollæ lacinia postica latiore emarginata, antheris exsertis, stigmata exserto bifido, fructibus amygdalinis, dense ferrugineo-tomentosis, embryonis radícula dense villosa.

A. tomentosa. Roxb. Fl. Ind. 3 88.?

Arbor. mediocris. Folia obtusissima. Flores ratione generis majusculi.

DESCR. Arbor. mediocris, ramulis articulatis. Folia opposita, obovata obtusissima coriacea integra utrinque glabra, subtus pallida.

Spicæ axillares, (et implices, terminales) ramosæ.

Flor. majusculi, oppositi inferiores distantes superiores conjesti: tribracteati.

Calyx profunde 5-partita lacin. oblongæ apice sphacelat ciliatæ, lacinia postica omnino exterior.

Cor. subrotata subregularis, 4-partita lacinia postica majore, emarginata carnosæ.

Stam. 4, sinus inserta, flam. subulat. one line long, Anth. bilocular. subcordatæ introrsæ basi affixæ.

Ovar. stylo reclinato, subulato.

Stigmata bifido oblongum : ferrugineo-pilosum : 1-loculare. Placenta centralis libera, 4-gona. Ovula 4, clavata, pendula ex apicem placentæ *inter angulos* apicem umbilicata, no distinction of coats.

Avicennia foliis obovatis glabris, subtus reticulatis fl. spicatis inferior distant. superior conjestis, (magnis) 3-bracteatis. Sepalis 5 5tum extima. Cor. lacinia postica latiore emarginata, filamentis mediocribus, anther exsertis, stigma bifida exserta, fructibus amygdalus dense ferrugine tomentosis, radícula dense villosa.

Although this has the leaves in shape as in *A. tomentosa*, Roxb. Fl. Ind. 3, 88, and though there are other marks of agreement, yet the leaves are perfectly smooth, and the flowers can not be said to be numerous.

After the corolla is fallen the style becomes much more reclinate.

Frutis like an almond, but more compressed, often inæquilateral surrounded at the base by bractes and calyx, covered with a dense velvet light ferruginous down, marked at the apex with a scar of the style and along both the edges with an obscure line. 1-valved ; coriaceous lined inside with a white delicate rice-papery cellular tissue.

Seed without any teguments, green, filling the whole cavity.

Cotyledons, conduplicate, one quite in the sinus of the other.

Radicle (after germination ?) much lengthened subclavate densely villaris.

HAB. In limosis inundatis Malacca.

Pl. CCCCXLVIII.

The development of the embryo presents in *Avicennia* great anomalies.

The ovula are nucleary.

The embryo sac Fig. I. when mature is curved within the point of the nucleus in the shape of a retort, or shepherd's crook. The line of the axis corresponds rather with the longer extension backwards, the recurved points however corresponds with the axis of the ovulum, appearing as if it were going to meet the fascicle of vessels that is to be found in the upper $\frac{1}{2}$ at least of the central denser tissue of the ovulum.

It is within the curve that all the changes take place, 1st in the formation of albumenary tissue, sometimes without application of boyaux, the long extension backwards and the recurved apex remaining unchanged the boyaux appear to pass into the crook, to a considerable depth nearly to the base of the recurved unchanged apex, they here appear *obscurely* to form the rudiments of a cellular mass, which is the future embryo, but is exceedingly indistinct, all these may occur within the ovulum.*

The albuminous mass enlarging forwards, soon protrudes, and rapidly assumes a considerable size.

Its aspect is cellular, shape flattened roundish, then a curved line appears, an semper, on its outer surface, from which the cotyledons soon protrude.

This mass continues to increase, the lower part preserving its thick, cellular appearance, the upper or that between the inner cotyledon and the nucleus becoming expanded, flattened, and cellular membranous.

The cotyledons become conduplicate at a rather early period, subsequently the whole of the embryo except the radicle is quite naked, that remains in its cavity in the fleshy base of the albuminous mass. Correspondingly, the posterior extension passes back into the placenta where it becomes dilated, and ramified, and exceedingly large.

So far as I have seen the recurved apex remains unchanged up to a latish period. Yet I have thought I have seen it

* I think I have seen in one instance grumous matter in the sac without any attachment of boyaux.

become smaller as the albuminous mass increased in size ; smaller certainly just as the cotyledons are going to protrude ; the nucleus undergoes no change.

1. The anomalies are, curvature of the embryo sac.

2. Protrusion of the albuminous mass beyond the ovulum, while the sac originally was internal.

3. The protrusion of the cotyledons, nakedness of embryo, but above all the direction of the radicle, the funiculus of which points to, and not from the apex of the nucleus, which also appears to be its direction at a every early period.

This also is well worthy of notice, as confirming the permanence of the direction of the radicle—that in the mature seed, its general direction is such as it would have been, had the cotyledons passed up inside the ovulum.

The anomaly of direction in the embryo, if the line of first appearance, which is axile, is considered is not so great as it would, at first sight appear. Although there is no appreciable mechanical cause, why the cotyledons assume so strange a direction.

Soon after evident impregnation, the fertilised ovule is twice as big as the others, is split open at its apex from which protrudes a fleshy soft roundish mass, and inside its pressure shews the presence of a roundish body.

The centre of the protruded mass is more membranocellulose, and to it, portions of tubes may be seen adhering.

During inflorescence, and even when the stigma is blackened the ovula (some times 3) are club-shaped with an umbilicate or lobed apex, from the centre of the umbilical cavity of one at least, an obscure small protrusion was observed ; the ovula appear solid : pressure however causes the escape the grumous fluid ; at this period a single tube may often be seen running down to the apex of the ovulum.

From the navel or sinus of the lobe, there appears to be an obscure channel leading to a less obscure cavity, towards

the centre of the ovulum, whether this has a lining membrane or not I cannot say, but its surface is irregular.

At a later period, but before the young fruit projects beyond the calyx, the protruded mass will be found larger (as well as the nucleus): from it near the nucleus and on its outer surface, projects a bilamilar body, which is the embryo, the protruded part about the fissure is membrano-cellular.

The two lamina are the cotyledons when detached, they are found to be even now unequal, the outer one being shorter, and arising as it were lower down the base of the placenta; opposite each end of each ovulum is conductile, but much more so opposite the fertilised ovule, the protruded mass of which seems to adhere to it, (*i. e.* to the conducting tissue.)

The protruded mass is more intimately connected with the nucleus by a gut or tube, which lines its central cavity. It is I imagine from the protruded end of this sac, that the protruded albuminous mass is formed, *it is highly divided*, so that it is a Santaloid tube inverted.

The shorter cotyledon is now bilobed, or biauriculate at the base.

The tubular portion internal to the nucleus appears to reach at least to its base; but it is difficult to ascertain its doing so, owing to the denseness of the tissue surrounding it, which forms as it were a column reaching throughout the ovulum. The apex of the protruded mass is cellulo-papillose. The tube certainly exists, and appears to be continued to the centre of the protruded mass.

The mass subsequently protruded, appears to be at one time enclosed within the apex of the nucleus, and the inner tube which is then tortuous, appears to be outside of the columnar tissue; even at this time the centre of the mass is discolored, and presents traces of the embryo, and its lax cells are obscurely traceable to the apex of the mass.

Judging from appearances, I should say, that the mass has

linear relations with the columnar central tissue, and that the tube is a subsequent formation being developed from the base of the mass, and running along between the column and that space of the ovulum next the placenta, that it is a lateral formation, that the mass is developed in a sac, arising from the end of the column—the embryonary sac, the communicating tube is branched at an early period.

Pl. CCCCXLVIII. Fig. VII.

a. The cellular substance evidently encloses the apex or upper half of the sac.

b. Base unchanged and I imagine from a single instance that it is thus.

c. Embryo sac.

d. Albuminous mass.

e. Certainly part of the sack.

f. Sac.

g. Albuminous mass.

h. End of boyaux entering.

i. Columnar centre.

j. Nucleus.

k. Less changed base of embryonary sac certainly closed.

l. Cellular mass just becoming protruded.

m. Embryo arising from a boyau (*assumed*).

n. Common tube.

o. The membrane of the sac is here and there traced.

At the time of inflorescence or very soon after, the columnar tissue is very evident, appearing to be continuous similar to that of the placenta; the situation of the sac is at this time occupied by opaque tissue.

After the protrusion of the cotyledons, the nucleus and subalbumen do not undergo much if any change, the cotyledons have commenced to be conduplicate, when twice as long as placenta, the nucleus when then unchanged in size is very hard, the subalbumen is enlarged, the radicle is still enclosed in it.

The communicating process is at this time easily separable.

There is no change of direction in the embryo, the protrusion being effected by the cotyledons, all that is required is a certain degree of obliquity as regards the nucleus or else they would pass it.

On a transverse section, have I seen in the placenta the dense central part with a tendency to be 4-lobed, but even at a later period, nothing like a section of the communicating posterior tube was observed.

It follows hence that the chief anomalies are the formation of the albuminous tissue outside the sac of the embryo, the penetration of this by boyau, the protrusion of the albuminous mass so formed, and the subsequent protrusion of the cotyledons.

The unique? ones are the formation of the albuminous mass outside the sac of the embryo, tho' the embryo is formed within the sac! and secondarily the *protrusion* of the cotyledons, the radicle remaining enclosed. Also the deposit of albuminous tissue on a sac, internal to the nucleus, and the laterality of the posterior extension.

To be carefully examined again, particularly with reference to the early state of embryo sac, the extent of the posterior communication, and to the embryo just before the cotyledons protrude.

LABIATÆ.

General remarks. It has for some time, struck me that neither Labiatæ nor Boragineæ are formed on a quarternary plan as to the carpella. I was first led to this opinion by observing in a series of observations, the constant relation between the number of vascular fascicles of the style, and that of the carpellary leaves entering into the formation of the Pistillum.

This view appears to have been hitherto neglected.

In the cases in which the number of vascular fascicles exceed that of the carpellary leaves, the law remains unchanged, owing to the evident arrangement of the bundles of vessels or fascicles into groups corresponding with the number of the carpellary leaves.

A still more obvious circumstance is to be taken into consideration, that is the number of styles. If we pass in review the whole of syncarpous orders, we find that the number of styles however united they may be, (and in this case only determinable by the number of vascular fascicles,) it is constantly the same as that of the number of carpella, and this law is most obvious in the gynobaseous orders. Further it remains to be proved whether in one single instance the carpellary leaf is developed into an ovary or portion of one, in which the style or stigma remains undeveloped.

Perhaps the contrary is the fact, the style or stigma being hence the most permanent part; of this I only know one instance, and that is in *Clypea* or rather *Cissampelos*.

The structure of Boragineæ and Labiatæ, is to be explained either by assuming the abortion of the styles, etc. of two carpella, or of their binary coalescence. The former explanation can scarcely be considered as sound, for there is not a single instance that can be adduced in its support. Of the latter there is no external (as indicated by furrows or lobes of the stigmata,) or internal evidence. The pistils

of Boragineæ and Labiatæ are therefore on grounds of all analogy of structure, formed on a binary plan. It only remains to explain how the anomalous structure arises.

A bilocular single carpellum may arise either from extreme inflection of the dorsal suture, (to which there is in many instances a tendency,) or of extreme inflection of the combined placentæ. But from the complete division of the two carpella that exists in the above two orders, as well as perhaps from the situation of the ovula, we are authorized in considering the anomaly as arising from complete inflection of the dorsal suture. Although in Verbenaceæ, Ehretiaceæ, Cordiaceæ, and etc., the quadrilocularity of the ovarium arises from an opposite cause. There is likewise another circumstance to be mentioned as pointing out the correctness of that which we have above stated, this is the almost universal basilarity of the styles. This shews that the lobed state of the carpella is more developed towards the geometrical apex, a fact in accordance with the structure of all syncarpous fruits. The only objection to this exists in *Cynoglossum*, in which the style proceeds from the geometrical, which, is hence the true apex.

It was perhaps from the consideration of this genus, that Brown in his *Prod.* describes the ovula as pendulous, hence shewing his usual extreme acuteness. I find in addition, that this is proved by taking into consideration the situation of the raphe. This in Labiatæ is next the axis, hence the lobes of the ovarium are not inverted, but in all Boragineæ except *Cynoglossum*, it is external with regard to the axis, proving that the lobes are inverted. It is highly curious, that in such, with one exception, there is an obvious tendency in the raphe to revert to its true site, viz., next the axis, since the foramen in all these is at the lowest point of the cavity, while the radicle of the mature seed points to the uppermost. The seed is hence adhering, and in its development describes a considerable portion of a circle.

Cordiaceæ in relation to what I have said above, require examination, since they have four stigmata. But this may arise from another cause, and one that has reference to the origin of the stigmata themselves.

Magong: April 17th, 1837.

PLECTRANTHUS.

Plectranthi sp. Pl. CCCCXLIX. Fig. II.

Caulis et prolongationes axis virides, fol. supra saturatviridia hinc illinc secus costa maculis albis irregularibus, subtus pallidis.

HAB. Bootan.

OCYMIUM.

Ocymii sp, Pl. CCCCXLIX. Fig. III.

1. Long section through 2 ovaries, shewing the situation of the raphe.
2. Ovulum, at the time of expansion.
3. Inner structure as demonstrated by pressure, nucleus and testa incorporated, no raphe.
4. Embryonary sac from an ovule, just after the fall of the corolla. This approaches to the membranous structure, is developed from the base of the nucleary cavity, but is distinctly cellular at its base, its apex is attenuated into a thin thread which communicates with the

apex of the nucleus, $\frac{1}{25}$ lens will scarcely demonstrate any cells except at its base, it is attached by a single cell; at the apex of the broad or dilated part is seen the embryo just forming.

5. Long section of an ovule more advanced, embryonary sac distinctly cellular.
6. Ovule viewed on its inner or raphal face, raphe evascular composed of fibres.
7. Long section of ovulum more advanced. Cotyledons opposite the raphe.
8. Portion of testa shewing the cellularity, of the nuclei.
9. Section longitud. of seed, thro' short diameter or at right angles with the axis.

This development is remarkable for the evolution of the embryo, at a distance from the foramen and apex of the nucleus.

The seeds have two integuments, testa and embryonary sac.

HAB. Affghanistan Quettah: *March 27th*, 1839.

1. *Boragineæ*, sp. Pl. CCCCLIV.'

I have omitted to number this Boragineous Plant, which is in some respects of singular structure, two of the nuts are much more echinate than the other two, in which there also exist a tendency to become of a cup-shaped form, a tendency by no means as usual in the *Boragineæ* of this country and which is carried to its maximum in certain forms of *Cynoglossoides*, and another beautiful species. The pendulousness of the ovula points out the affinity of this plant to *Cynoglossum* and its associates, and I think the structure of the scales points out a greater than usual tendency to glandular and hence the staminal structure.

13. Long section of ovary.
- 13a. Ovulum.
14. Ovule and interior of ovary from a bud, corolla length of bractea shewing that the conducting tissue is formed at an early period, not a sudden appearance at the time of fecundation.
15. Young fruit, shewing the separation of petals and stamina from the glandular cup, a fact analogous to what occurs in *Mirabilis*.
15. Pistillum of do.
16. Calyx of fruit, in a young state.
- 16a. Same laid open, shewing the inflexion of the marcescent petals etc.

HAB. Affghanistan. Barren, rocky hills. Cabul et alibi.

OBS. Each flower to be looked on as terminal, owing to the presence of a bud in the axil of the last bractea.

The inflorescence only differs in degree from the paniculate or corymbose forms; in principle it is the same. Three or four other species of similar habit have been obtained by me, but only one of the paniculate form.

The conducting process is of early origin, and is at an early stage applied to the foramen, it is a formation from the stigmatic tissue. Lindley's explanation is not correct, the strap is never broad enough to hinder the process from entering the foramen.

EHRETIACEÆ.

EHRETIA.

Ehretia serrata, Pl. CCCCLIX.

Calyx, 5-partitus, æstivatione imbricatio.

Cor. 5 partita, æstivatione imbricata.

Stam, tot quot laciniae corollae iis alternæ, tubi brevi basin prope affixa, introrsa. Antheræ dorso affixæ biloculæ. Venatio corollæ normalis, filamenta vasculosa.

Stylus vasculis 2 donatus. Stigmata 2 subcapitatae, canali infra in unum coalescenti.

Ovar. 4 locale (spuria) ovula in oculis solitaria pendula, foramen superum hilum prope.

Inflorescentia paniculata, floribus nudis sessilibus in paniculae ramis, sæpe aggregatis, *Ehretia serrata* Roxb. Vix *Ehretiae* sp.

1. Alabastrum.

2. Flower.

3. Corolla laid open.

4. Calyx and Pistillum.

5. Stamen back view of.

5a. Ditto front or inner.

6. Pollen viewed opaquely.

6a. Ditto in water $\frac{1}{20}$.

7. Ovar. long section.

7a. Ditto shewing the conformation.

8. Ov. transverse section of the placentæ etc.

8a. Ditto towards apex.

9. Ovula.

OBS. The ovary is formed on a similar plan as that of some Verbenaceæ, the placentæ being involute and closely united, and towards the base of the ovary produced so far outwards as to divide each cell into two.

There is no line to indicate the separation of the two carpellary leaves, although there is an evident one travers-

ing the placentæ in the direction of their inflexion from the centre.

General remarks. The number of vascular fascicles of the style at once points out the binary formation of the ovary : but it is worth while examining, those species of *Cordia* which have *twice cleft styles* according to Roxburgh. And it is still further doubtful in taking the number of fascicles of the style into consideration, whether Labiatae and Boragineae have not their ovaria formed on a binary, and not on a quaternary plan.

Cordiaceae are represented in India by several species, all are fruticose, and most, arboreous. They have but few sensible properties. See, *Sebestina Myxa*, and *latifolia*. The flowers are often odorous.

One species performs the same office, although in a smaller degree as *Arundo arenaria* etc. do in Europe, that is, binding together loose soil.

They are generally natives of Hills, and of rather high latitudes.

The leaves are remarkable for the extreme extent of the ramifications of the veins. So much so that the space occupied by these organs, perhaps exceeds that occupied by those of aëration.

None except *Ehretia arenarium*, *mihi*, which is found between 12° and 28° N. appear to have a very wide distribution.

Lindley characterised Cordiaceae by a four cleft stigma, if this be the case, the style remaining undivided is a proof that the stigmata are prolongations of the placentæ. No one can explain the ovary of these orders by assuming only one carpellary leaf to be abortive. As I have long observed, this origin of the stigmata and the number of vascular fascicles of the style are worthy of great consideration, the latter in relation to the number of component parts of the ovary.

The flowers are occasionally polygamous as in *C. Myxa*, in

which likewise there are no bractæ, not even to the primary divisions of inflorescence. In this species there is a tendency in the inflorescence to become unilateral and recurved.

COMPOSITÆ.

General Remarks.

The inflorescence, or rather each capitulum is always terminal, that is, it either terminates the axis itself, or one of its axillary branches. The terminal one is invariably developed first; its origin is occasionally observed by the continuation of the axis, owing to the development of a branch in the axilla of the opposite leaf, as in *Eclipta*.

Is any stress to be laid on the external dilatation of the apex of the peduncle? when present it gives an idea of a multi-partite, not a polyphyllous involucre.

Can the union of the ovary to the calyx be identified by the number of layers visible on a transverse section, as in those with biseriate pappus, and *no.* (1) 401, p. 230 in which the limb of the calyx is annular, the pappus arising internally.

Link I think lays some stress upon the distinction between pappus and paleæ of the receptacle,—what is it?

Plumose pappus is only an excess of development of the dentata.

Can the difference between a tubular corolla, and that which arises from an abortion of the *ligula* be always distinguished by the papillose oblique mouth of the latter?

What do these papillæ represent, are they always present in those in which the ligula is imperfectly developed? and which I take to be the case whenever the vascular fascicles are imperfectly developed. In such case they will represent lobes of the corolla: vice-versa are they absent in those, in which the ligula may be supposed to be perfect, what is the cause of a ligulate corolla, and what is its æstivation?

Mr. Brown says that the vessels unite with the apices of each lacinia. In those which I have examined this is not the case.

To what is the cohesion of the anthers to be attributed? particularly in those cases in which the substance of their cells seems to pass into each other.

They can scarcely, be distinct in an early stage.

The difference in the form of the stigmata in the radical and discal flowers of those in which the former are imperfectly corolline, or perhaps in all radiate, is worthy of notice, and points out an imperfection pervading every part, but the ovula excepted.

Is much dependence to be placed on the articulation of the style in *Carduaceæ*? This occurs in all, and its distinctness here only depends on the great development of the epigynous disk.

Has the style invariably 2 vascular bundles, indicating its binary composition ?

How is fecundation effected ?

In several the ovula cohere, at least partially with the ovaria, this is however not of much importance, since the seeds appear to be invariably free. *Prenanthes no. (2) 445*, p. 251 however leads me to suppose, that the seed may appear perfectly free, while in fact the testa adheres to the pericarp ; this is not the case in the example cited. If this be true, the immediate covering or the apparent testa will be due either to the remains of the nucleus, or to the embryonary sac ; in *Prenanthes* the latter is the case.

All that I have hitherto examined agree in the singleness of the integument and its intimate cohesion with the nucleus. They all agree in the mode of development of the embryonary sac which is attached by both its extremities, but chiefly by its base, and in the first appearance of this as a vesicle, at the apex of the nucleus.

The embryo however appears to be formed about its middle, instead of its apex as in usually the case. With respect to the raphe, they seem to differ, in some I cannot find it at all, in others it is developed gradually, and in these it appears to be generally, if not always complete, terminating in the margin of the foramen. The embryonary sac is very large in *Prenanthes, no. (2) 445*. p. 251.

Burrumpootur : *March 23rd*, 1836.

I am still more inclined to doubt the fruit being an *Akenium* ; in every instance the testa coheres to the pericarpium. This is at once proved by the presence of the raphe on parts of it, when detached from its cohesion. The cellular membranous coat enveloping the embryo, owes its origin to the embryonary sac ; this is at once evident by its having at both ends, remains of its original attachment. The nucleus, which however is never distinct, disappears altogether.

Although the transition from the perfect flowers of the disc, to those of the imperfect radial ones in those cases in

which all the flowers are tubular, is sudden ; still the peripheral ones are more imperfect as to size at least, than the inner ones. Perhaps such should immediately follow *Carduaceæ*, particularly as many have appendages to the anthers, on the apical one, however I think very little stress is to be laid.

Thus beginning with *Carduaceæ*, we should pass on the *Corymbiferæ* commencing with those in which the radical flowers are tubular, thence to the *Radiatæ* through *Erigeron* or those genera which either have ligulate, or evidently a ligulate tendency, but in which either no ray at all is developed, or developed merely on the circumference, and thence to the true *Ligulatæ*, keeping up the chain with reference to the greater or less development of the radius.

Carduaceæ certainly are the most perfect, and *Ligulatæ* are the next.

Considerable mutability resides in the involucra, and the fact of their becoming incurved when the florets are removed for the examination of the receptacle, shews admirable design. Their contraction, for such it certainly is, although probably limited to one surface, is very distinct and strong

Is there any thing definite in the number of the pappus ?

There is an obvious relation between the development of the epigynous disk and the stamina, for the disk is only developed to any degree in the hermaphrodite flowers—the only ones I have yet examined on this point. This is what one would have expected, the disk being a staminal organ.

The composition of the inflorescence has been shewn in every instance hitherto examined by me, except *Sphæranthes* in which it is centripetal, so far at least as the aggregate is concerned. In the others, the central and really terminal head is always first in development, so that it may be laid down as a rule, that all simple inflorescences are centripetal ; all compound centrifugal.

The fact of the inflorescence of *Sphæranthus* being cen-

tripetal, both *en masse* and in detail, proves that it is a single capitulum, hence the generic character of Sprengel is nearly correct, although there is no true anthodium. It likewise suggests a certain affinity with Echinops.

That the paleæ of a receptacle are merely modified scales of the involucre, in other words, bractæ, is proved by their absence in those floscules which arise from the axillæ of the inner scales. Here again Sphæranthus is interesting, it has no involucre, because all the axillæ produce capitula.

With regard to inflorescence, that of Gramineæ is not simple, but compound, the spiculæ of the spikes being most developed towards the apex, in other words terminal locustæ are the first developed.

Burrumpootur: *March 29th*, 1836.

The development of the ligulate flowers of Compositæ is connected with a very great enlargement of the lacinia of the corolla. The development is centripetal, that is, two of the most distant lacinia first take it up, and the central one the last. This may take place in such a degree that the central lacinia, or even those next to it may become obliterated, and this is partly (perhaps) the case whenever the number of teeth is less than 5.

The centripetal development is so strong, that the outer half of a lacinia may become ligulate, and the inner not, so that any amount of irregularity as to the number and size of teeth may be expected in a ligulate corolla.

A ligulate corolla can only occur in a flower with strictly valvate æstivation, and its great prevalence in the order, is a proof of the constancy of this æstivation, and consequently its value as a character. Why the corolla becomes unilabiate is another question, it may arise from the pressure which growth in any other direction than outwardly, may be supposed to be subjected to, and this idea is somewhat corroborated by the frequent limitation of ligulate corollas to the circumference of the flower. Then the question arises, why does it happen, that one grand division of the order is cha-

racterised by having all its flowers ligulate. This is a question worthy of examination, for it appears to my limited experience, that in both those tribes which are characterised by having entirely regular, or entirely labiate flowers, that the amount of pressure due to the structure of the involucre is greater than in the third or mixed tribe.

It must not be overlooked that the degree of development of ligulate flowers, is in the ratio of their distance from the centre.

The maximum growth is in most cases around the circumference; take for instance *Centaurea*, and this may also be looked upon as an evidence in favour of the general tendency to produce ligulate circumferential flowers. This tendency is very evident in *Calendula vulgaris*, in certain specimens of which, but very few flowers in the centre of the disc remain unchanged, and it is equally so in a vast number of others, in which, although the flowers of the circumference are less developed than those of the centre, yet there is an obvious tendency to become unilabiate. The two lacineæ that in *Calendula* take on the irregular growth are the two nearest the axis, and it appears to be a condition, and indeed one without which the lip would have a reversed directions, that while they continue entirely distinct from each other, they cohere more or less with the teeth nearest to them. Thus whenever a lacinea is wanting, it is the 5th.

The tendency to ligulation is always accompanied by a higher degree of coloration. Thus in *Calendula*, the first change that takes place consists in the laciniae nearest the axis, or their inner halves with respect to the axis, assuming an orange, in lieu of their original yellow colour.

Granting the tendency to separation between these two laciniae, and a tendency to adhesion or even obliteration of all or part of the others, the corolla must necessarily become more or less unilabiate, particularly when combined with a certain extra development.

In all cases where ligulation is not the essence of the formation of a compound flower, it is accompanied by a reduction even to total obliteration of the stamina, an argument in favour of the affinity in nature, between the stamina and petals. This is particularly evident in *Calendula vulgaris*, in which the slightest tendency to ligulation is accompanied by abortion or at any rate, want of power in the male organs. And hence perhaps this tendency to ligulation may almost be expected to be greater in those plants of the order, in which the ligulate florets of the ray are entirely neuter. This is also pointed out by certain regular flowered genera such as *Centaurea*, in which the extra development of the radiate flowers is associated with loss of sexual power, but it is not only the actual over-development that is attended with this effect, but also the slightest tendency to unilabiate flowers in a host of *Corymbiferae*.

Von Buch's theory is too partially supported by facts to entitle it to be adopted in so general a matter, as the production of ligulate flowers in *Compositæ*.

In *Cichorium** there is a singularity connected with the anthers, from the midrib of each of which, a remarkably fine membrane is produced, which contracts a firm adhesion with the similar productions of the antheræ of either side; along the line of union is a dark line simulating at first sight a line due to vascularity; these membranes are quite distinct from the other part of the anthers. They are produced only from the connection of the polliniferous portion of the anther. See Pl. CCCCLXVI. Fig. *d*.

The structure of the base of the style is only in excess of that which occurs in all truly adhering calyces, and is I consider, evidence of a tendency to produce additional stamina, the quantity of this glandular substance varies much; in *Cichorium*, it is highly developed.

* *Cichorium* resembles very much in habit, certain forms of *Campanulaceæ*.

There is a tendency even in genuine *Carduaceæ* to irregularity of the flowers of the circumference, hence the question, which is the typical form of *Compositæ*? Is it that in which this tendency is carried into full effect, as in *Ligulatæ*, or is it that which possesses the greatest regularity, and consequently that in which it is least worked out, as *Carduaceæ* etc., or is it that in this which general tendency is executed, as well as another less general—namely, the tendency to regularity as we approach the centre—*Corymbiferæ*. This question can only be decided by examination of the whole order. I am almost persuaded that there are three types of formation of different value, which will be found to pass into each other at various points to a greater or less degree. These types are pointed out by structure, as well as by sensible properties, or the want of these, which last occurs in *Carduaceæ* or *Cynarocephalæ*, while *Ligulatæ* are milky, and *Corymbiferæ* very generally aromatic and glandular.

In a species of *Carduus* from Candehar, the florets in a very young state consist of a calyx with a rudimentary toothed limb, a valvate corolla nearly partite to its base, and 5 smaller similar bodies, the rudiment of the anthers. Traces of a female organ are evident, in the form of a small central projection, but no ovulum, see Pl. CCCCLXVI. Fig. h. The development appears to be equal except as to pollen, which is of late formation.

The subsequent changes take place with too much rapidity to be observed in their several stages.

The stigmata of *Anthemidea* 638,* or rather the stigmatic surfaces of the branches of the style are peculiar, and rather incompatible with the idea that the stigma is the denuded apex of the midrib, for it is plain, that the stigmatic surfaces are confined to the margins of each branch, these becoming confluent and very distinctly papillose at the apex Pl. CCCCLXVI. Fig. c.

* Itinerary Notes p. 273.

To reconcile this with the actual idea of a stigma ; we should have to assume, that the stigmatic surface was least developed at the spot from which it is said to originate, because the papilla are more developed on the sides of the apex, than on its centre, and then again to assume its decurrence down the style. Such an idea of the structure and origin of the stigma, sets out with the improbability, that from the most fibrous and the most dense portion of the structure of an ovarium, the most cellular and the most lax portion should originate. Considering the stigmatic surfaces as productions from the placentæ, we obviate these difficulties, and more, we render every apparently anomalous instance capable of easy and direct explanation. If that portion of the ovarial leaf which forms the style be spread out, or is otherwise not involute, the stigmatic surface will be external, it may be either marginal as in the instance alluded to, or it may, by mutual adhesion, occupy the whole inner surface.

If the style be involute to that degree that its outer edges are brought into juxta position, the stigmatic surface will occupy to a greater or less degree the centre of the canal so formed. Were the stigmatic surface to originate from the apex of the midrib, it could not have such relations to the placentæ as would insure the shortest road to the completion of fecundation, and in this point of view the theory is very faulty.

In this same plant there is an obvious attempt to form the rudiment of a calycine limb, while in some others (instead of such being the case) the base of the corolla grows downwards over the ovary. Pl. CCCCLXVI. Fig. *g*.

In *Carthamoides* 639*, there is a tendency to abortion in the female part of the flowers of the ray ; the stigmata being comparatively small. Even in the disc, the branches of the style are firmly united and papillose over all their exposed surfaces, except towards their apices, which are smoothest, and

* Itinerary Notes p. 273.

on which the true stigmatic surfaces are somewhat indistinct. The anthers have the peculiar fine connectival membrane, and the stuposity towards the apex of the filament. The cessation of the vessels at the commencement of the peculiar structure is evident, as well as the nature of this peculiar structure itself, which is built up of short quadrate cells.

In *Centaurea* 640*, the connectival membrane exists, the structure of the stamine is very much the same, but there is no stuposity, the glandular disk is much developed while the base of the style is not bulbous, the curvature of the corolla in *Carduaceæ* is worthy of notice, for it is very common.

Affghanistan, May; 1840.

ELEPHANTOPUS.

Elephantopus sp.

Herbacea spithamæa, hispida, fol. rosacea patentibus ad bases caulim confertis oblongis, subsessilibus repandis, serratis basibus dilatatis ciliatisque, summis subintegris intermediis lyratim 2-3 divis, floribus capitatis, capitulatis terminalibus, foliis 3-5 cordatis concavis involucretis.

Ejusdem generis cum, *no.* 436.

SPÆRANTHES.

Spæranthus.

Herbacea ramosa decumbenti-prostrata, pubescenti-viscosa, fol. decurrentibus oblongo-lanceolatis dentatis serratis, serraturis aristatis. Capitulis sphæricis ovato-globosis rubris.

Axis conica, obtusa, medio lacunosa. Capitula composita e glomerulis indefinitis discretis subsessilibus extus involu-cellatis, squamis oblongo-linearibus 1-seriatis plus minus scariosis pilosis ciliatisque.

Floribus heterogamis, exterioribus 1-seriatis, sub 10 fæmineis, interioribus 3 hermaphroditis. Radii tubulosi, sub-irregulariter 3-fidi, ore haud obliquo. Stigmata subulata, subexserta. Disci tubulosi multo majores, sæpius 4, ore parum ampliato 5-fido, venatio Brun. vena recurrente 0.

Stam. totidem alternantia. Filam. filiformia una basi corollæ inserta. Anther ovato-oblongæ simplicis vel nec appendiculatæ. Stylus exsertus basi bulbosus vasc. fasc. basi etiam discretis ad anthesin cito elongatus $\frac{1}{2}$ superior pilosus. Stigmata 2 brevia ratione fæminearum approximata. Pollen globos. hispidum. Ovaria teretiuscula pilosa, ovula erecta libera, raphe 0.

HAB. Assam. In arenosis Burrumpootur: *March 25th*, 1836. no. 450.

Squamis conformis unica capitulas. Inflorescentia spicæ centripeta ut etiam capitulosa? vici semel stigmat. tria vasc. fascic. 3 stylo, quorum 2 approximata quamvis discreta.

CHAR. Capituli dense spicati, pauciflori heterogami, bractea unica suffulta; squamæ scariosæ, ciliatæ, biseriatæ.

Flosculi tubulosi, radii fæminei, disci sub 4 hermaphrodit. Filamenta basin corollæ inserta! Pappus 0. Styli hermaphroditi pilosi.

OBS. 1. This overrules DeCand. sections, as it belongs to his *Eusphæranthus*, although the axis is hollow, see Wight's Contr. p. 11.

2. The characters of Jussieu and Sprengel are both erroneous, although Jussieu's is far the best, as there is only one scale which does not separate with each capitulum, and as it is inferior to each, it is certainly a bractea, and belongs to the axis of inflorescence. All the rest are referable to the capitula. There is no common involucre, at least more than resulting from the outermost bractea.

3. It is entirely a Corymbifera, its peculiarity being the aggregation of its capitula.

CONYZA *Juss.*

1. *Conyzæ* sp.

Herba annua erecta bipedalis cano-villosa, foliis alternis obovato-spathulatis sessilibus runcinatis dentatisque vel dentatis et repandis.

Cymis axillaribus terminalibusque pluri-capitulatis, subdichotomis capitulis nutantibus, centralibus prius evolutis subcylindraceis medio angustatis.

Involucr. imbricat. pluriseriatum.

Receptaculum planiusculum, favulosum, heterogonum. Flores radii multiseriati fæminei tubulosi, interiores magis evoluti ore dilatato 3-fido, laciniis papilloso-cellulosis. Stigmata linearia exserta angusta minute papillosa.

Disci pauci tubulosi lutei, faucibus paululum ampliatis 5-fidis, æstivat. valvati, vena excurrente nulla. Stam. infra medium tubo inserta. Anth. basi apiceque appendiculatæ, appendiculis basi setiformibus apicis plano-subtruncatis.

Stylus basi bulbosus, stigmata 2 subexserta, valide papillosa. Ovaria cylindracea, pubescentia. Pappus dentatus simpliciter serie, os calycis simplex obsoletusque. Raphe ad epocham fecundationes seminis apicem vix attingent.

Akenia subimmatura oblongo-cylindracea vix compressa pubescentia.

Testa pericarpio adnata et vix sine laceratione solubilis raphe normalis.

GNAPHALIUM.

1. *Gnaphalii* sp. Pl. CCCCLXVII.

Planta spithamæa, sericeo-canescens. Ramis subradiatis
lateralibus basi decumbentibus centrali erecto.

Folia linearia vel lineari-spathulata varia torta, summa
circa inflorescentiam aggregata subverticillata.

Capitulum aggregationes terminales, interdum ob elon-
gationem rami ex axillis folii supremi unius tantum videntur la-
teratis. Capitulus quisque subovatus terminalis prius evo-
lutus.

Squamis exterioribus laxis imbricatis subdistantibus vere
spicatis, longe cuspidatis, cuspidate-reflexiusculo, carinato-
concava margine membranam reflexo, dorso arachnoideis.

Intimis e cuspidatis, subglabris.

Receptaculum cæterum nudum.

Flores forminei, in axillis squamarum exteriorum cons-
tantes, ex ovario subglanduloso. Corolla anguste tubu-

losa, apice obsoliti 3-loba et stylo ordinario ramis exsertis. Flores squamarum interiorum pappigeri abortivi, stylo in tubo incluso.

Flores summi masculi, vere terminales? in receptaculo rugoso nudi an ob abortion. squamarum radii. Ovarium ut in floribus fæmin. abortionis. Pappus idem, dentatus. Corolla tubulosa, apice 4-fida, venatio Brunoniana. Antheræ 4, basi et apice, appendiculatæ, medium tubi versus exsertæ, Stylus clavatus apice pubescens.

Fructus oblongus subcompressus, corolla in axillis squamarum exteriorum et stylo dentius persistente, hujus ramis forsitan elongatis, glandulosum.

Seminis tegumenti unicum embryonarium solubile. Embryo ordinis.

1. Plant natural sige.
2. Head of inflorescence.
3. One of its component parts detached.
4. Portion of do. shewing the structure of the capitulum.
5. Portion of do. shewing the nakedness of the male flowers, the suffultion by a bracte of the remainder, and the change in structure in these as we proceed upwards.
6. Female flowers and its bracte, the stigmata are anterior and posterior.
7. Female flower detached shewing the want of pappus, and the small development of the corolla.
- 7a. Ovarium viewed under pressure.
 - a. Calyx, its wall glandular colored and furnished with two vascular facicles which send two branches into the corolla, and a corresponding number to the style.
 - b. Very fine evascular pure *membrane* which I consider to be the ovarian wall and which is detachable by pressure, although evidently attached to the base of the style, c. ovule.
8. Imaginary section of female flower not carried through the ovulum. I will not answer for the correctness of the situation of the ovule.

9. Abortive flower from the axil of one of the inner scales. Pappus well developed. Corolla badly so, dentate at apex, and enclosing within it an obscurely emarginate style.
- 9a. Imaginary section of do. not carried through the ovary.
10. Male flower. 11. Section of do. not carried through ovary. Pappus chiefly removed. The ovula of both such flowers, (9 and 10) are abortive, or rather come to nothing. .
11. Anther back view of. Filaments evascular ! 10b. Pappus portion of.
12. Fruits. 12a. Same, corolla and Style lapsed, the branches of the style and their corresponding stigmatic surface appear to enlarge or elongate at least after impregnation.
12. Shews the structure of the coats of the akenuim, a genuine one in this instance although the inner coat is separable, *a* calycine coat, *b* embryonary sacculate, so that the ovarial coat, the testa, and nucleary coat have disappeared.
13. Section of fruit, *a* ovarial coat, *b* that derived from the embryonary sac, *c* embryo.
14. Portion of arachnoid threads.

Candahar: *May*, 1839.

HAB. Candahar Affganisthan, see Itin. Notes p. 272, no. 632. A tendency in Gnaphalium to have radiate ramification.

Obs. This is an interesting plant, inasmuch as it points out the tendency in the female flowers to be external, their tendency to be provided with bractes, to have no pappus, and small development of the corolla, and total abortion of male organs. It shews, that in such instances there is a gradual change of development towards the interior of the capitulus, those flowers which are provided with bractes and situated interiorly, being abortive and having pappus, but still without a trace of male organs. It shews that in some cases the male flowers are more

terminal than the female, and that the female organ is far more permanent than the male, since these are provided, with rudiments of females, indeed to a considerable amount of development.

The change of structure towards the apex of the filament appears due to a condensation of structure, no fibrous cells exist in the anther, which however dehisces perfectly. The filaments are evascular. The venation of the corolla is Brunonian. The structure of the ovarium is very curious and merits further investigation. If the membranous separable inner coats be really the ovarium, it forms a transition to certain cases of Dipsacæ and Scævoleæ, it affords a most anomalous instance of the possibility of the style being vascular, while the ovarium is evascular.

Of the structure of the fruit I have little doubt; the outer tegument of the akenuim appears to me to be calycine, the inner belongs to the embryonary sac, which there is some reason for supposing to be the most permanent coat of an ovulum, as it is the last in formation, its structure in Compositæ is peculiar, consisting of a single series of cells, each of which has a grumous nucleus.

There is considerable affinity, between this *Gnaphalioideæ* and the monocotyledonous-looking plant of the same order, from Abigoon, see Itinerary Notes p. 232, no. 231. And I may here mention that this transitional appearance exists at its maximum, in a plant, which I suspect to be Roxburgh's *Æthulia axillaris*.

2. *Gnaphalii* sp. Pl. CCCCLXVIII.

Planta minima canescens radiati-ramosa. Folia ad basin caulis et subinflorescentias aggregata, linearia revoluta vel patent. Capituli compositi dense arachnoidei nivei. Partialis subrotundis, paucifloris. Squamis cymbiformibus marginibus approximatis et arachna dense quasi clausis, ore tantum obscure hiantibus, extimis minoribus 5 intimis subverticillatis radiatis, exceptis omnibus fæmineis.

Flos fæmineus e corolla angust tubulosa obscure 3-dentata, ovario glabriusculo, stylo stigmatibus ordinis, extimis abortivis.

Flores masculi discoidei pauci 3-4, terminalis squamis 5 intimis vacuis circumcincti; structu ordinario. Pappo pareo dentato. Antheris subinclusis.

Akenia reconditi in sinubus squamarum obovati, compressiusculi, lævia glabra tegument bina, exterius calycinum lutescens, interius grumoso-areolatum (ex embryones sacco ortum) Embryo ordinis.

1. Plant natural size.
2. Capitulus single separated.
3. Same, some squamæ removed, the others separated, the 5 upper ones subverticillate somewhat spread out.
4. Another view the 5 upper squamæ as seen in the dry state: the arachne supposed to be removed, it shews the small development of the outermost squamæ and their flowers, the want of flowers to the verticillate ones.
5. Female flower and scale, which contains the whole of the flower, except the apex of corolla, and the stigmatiferous branches of the style. 5a Female flower.
6. Male flower.
7. Same spread open.
8. Portion of Pappus.
9. Anthera.
10. Portion of wall of its cell, the fibres rudimentary and quite wanting in the basilar appendages.
11. Akenuim, which is quite smooth.
12. Section of ditto. A calycine tegument. b Embryonary. c Embryo.
13. Portion of tegument of akenuim. a Calycine. b embryonary saccular.

HAB. Candahar: *May*, 1839. Vid. Itin. Notes no. 633, p. 272.

Obs. The chief points worthy of notice are the small de-

velopment of the outer scales and their flowers; the want of female flowers to the innermost ones, their verticillation and distance from the female scales, and relations to the male flowers, and the small development of pappus of these.

From no. (1) 632, it differs subgenerically at least in the above points except perhaps the first,

As the scales, which appear always to be 5, around the male flowers, although similar structure to those containing the female flowers are always empty, it is a point of enquiry whether the male flowers are developed in their axillæ or not. This I have been unable to do owing to the age and withering of the single specimen I have found. But as in (1) 632 there is an evident tendency in the innermost scales to have abortive female flowers, there is no reason why that tendency should not be complete in this instance.

The spicate inflorescence of the female, and the capitulate do. of the male, is well shewn in this plant, and judging from this we should not be surprised at finding a Composita with obviously spicate female flowers, and more or less distant, (perhaps involucrate) capitulum of males.

Is not the tendency to have the axis of inflorescence terminated by male flowers universal in the order. Are not the males of the really terminal capitulus more numerous than the lateral ones?

The vascularity of this plant is small, the marginal veins of the lacineæ of the corolla being obsolete, at least under a lens $\frac{1}{10}$ focal distance, the vessels of the fruit are very indistinct, and none? exist in the stamina. The stigmatose branches of the style are well developed in the male flowers and it would appear that in most such instances these branches are more papillose than the true ones.

3. *Gnaphali* sp.

Ovulum ascendens, e nucleo tantum. Funiculus brevis. axin proximis et raphe brevis, apex nuclei, hilum prope.

Fructus?

HABIT. Affghanistan in collibus sterilioribus inter axes et in super rupes, vulgatim per totam plagam Khorasanensem.

This is a very curious plant, agreeing with *Galium* in every thing, but its bracteate involucred flowers, very sepaloid perianth, and the abortion of the inner cell of the ovary. There are many points that it presents for consideration.

Obliquity, from abortion of some of the leaves of the whorl, producing the inflorescence. The curious bractæ. The perianth, the epigynous disk. The very curious structure of the inner layer of each cell of the ovary. The constant abortion of the inner of these, and the reduction of the ovula to a nucleus.

There can be no doubt in this plant, of the nature of the perianth, which is sepaloid from its situation and natural colour, it therefore becomes necessary to revert to *Galium*, and its congeners, to enquire into the true nature of their inflorescence, and structure of the layer lining the cells of the ovary: I know of no other instance.

This performs every office of a tegument to the ovulum during its younger stages, and as the testa occasionally does, it becomes during the formation of the seed, so fine, as to be scarcely, if at all demonstrable; it may readily be mistaken for a testa or tegument, especially if carelessly dissected, but its existence in the barren cell, and its being perfectly closed, demonstrate that it does not belong to the ovulum, independently of the considerations derived from study of the development of this, and its entire structure.

Fig. I.

1. Plant natural size, radicles reddish as madder.
2. Florescence, one bracte and its flower removed to shew the nakedness of the central flower.
3. Lateral flower and bracte.
4. Perianth just opening,—shewing the æstivation.
5. Flower, just before expansion.
6. Expanded flower, 6a Perianth and genetalia viewed vertically.
7. Inner view of anthers before dehiscence.
- 8, 8. Inner, outer, and lateral view of stamina after do.
9. Pollen too minute for $\frac{1}{25}$ lens.
10. Long section of flower anthers removed.
11. Style and stigmata.
12. One of the hairs of the outer layer of ovary.
13. Long section of the ovary, shewing the closed nature of the inner membrane (not oblique as it should be.)
- 13a. Preparation younger state, shewing the same.
14. Ovulum, 14a its apex.

Fig. II.

1. Flower just at expansion.
2. Ovary or pistillum, calyx then removed.
3. Nucleus probably accidental, although the cohesion of the tube was finished, no other instance occurred.

4. Shews development of ovula, *a* placenta and septum, portion of, *b b* portions of the outer layer of which the calyx is a direct continuation; inner layer *d*, *a* nucleus, *d* funicle, *e* embryonary sac, *f* embryo.
5. Some more advanced, the same letters have the same references; *f*, a detached embryo (not enlarged enough) young to shew the nature of its pedicel.
6. Very young ovary laid open *a* outer layer, *b* inner ditto, closely investing the ovula *c*.
- 6*a*. Ovule, *c* detached.
7. More advanced, the same letters, have the same references.
8. Inner membrane which bursts instantly towards its upper end.
9. Young fruit, *a* outer layer, *b* inner do., *c* nucleary do. cohering with it, *d* hyaline margin of albumen, *e* albumen, *f* embryo (a plan) a section being impossible.
- 9*a*. Embryonary sac—albumen and embryo, this is shewn artificially.
- 9*b*. Portion of its albumen near the margin.
10. Same, more advanced, *a* outer layer, *b* inner now composed of inner excessively fine and nucleary membrane cohering intimately, *c* albumen, *d* embryo.

Those leaves are abortive that are on the opposite side of the stem to the inflorescence, it follows hence that as the inflorescence is unilateral one side of the stem throughout its flower-bearing portion, will produce leaves, the other flowers; of the leaves, one axil is empty; the other bears alternately a flower bud.

The inflorescence although tending to the umbellate form, is a true compound raceme, its form is curious, in as much as it presents none of that irregularity so prevalent in cymes, to which class it obviously belongs. We may therefore meet with one flowered species, in which case no bractes will be developed, or we may meet with a one flowered species, with bractes, but these empty.

In one instance, one of the lateral flowers had pedicels, on its inner side with a flower developed, and as this was much smaller than that in the axilla of the leaf, we may conclude that the flowers are all terminal, or rather that each lateral flower-bud may become a simple raceme.

In *Galium*, the carpella are both developed, and both lobes of the disk are equal, in the more petaloid species of this genus, the perianth separates all round the base, of the albumen.

From casual examination I think that the inner membrane is distinctly visible in the fruit.

Throughout all the stages, I have examined of the development of the ovulum, and these include very minute buds: it would appear that the ovulum consists of a nucleus alone; the same organisation exists in *Galium*, and probably in some? *Rubiaceæ*. Within is developed an embryonary sac of that form which I call albuminary, and the nucleus becomes at last reduced to a thin coat, cohering most intimately with the inner layer alluded to, and also slightly with the external or calycine? layer, so that the albumen *i. e.* the seed, has no demonstrable covering.

The membranous nature of the embryonary sac, which I should observe is of late formation, *i. e.* it does not exist before impregnation, is well seen in the nearly mature albumen, which presents a hyaline membrano-mucous-looking edge.

In this sac, opaque grumous grains of albumen are copiously developed.

It follows that the usual account of *Galium* are altogether wrong; on this head it will be necessary to examine *Decaïnes Rubia*.

The nucleary ovule, and the reduction of the perianth forcibly call to mind *Santalaceæ*, from which it is removed in the first place by the relation of the stamina to the perianth, and in a less degree by the bilocularity of the ovary.

Organisation seem to be much lower than in *Galium*? the stamina and the styles being altogether cellular, this last is a very unusual circumstance.

CAPRIFOLIACEA.

LONICERA.

Lonicera sp. Pl. CCCCLXXX. Fig. II.

Frutex pygmæus, prostratis, ramis brevibus ascendentibus. Cortex alba sæpe fibroso-lacerata. Ramula compressa.

Fol. subsessilia coriacea linearia obtusa 1-venia, siccitati margine recurva. Petioli brevissimi basin dilatati et saltem juniores in annuli coaliti.

Flores bini in pedunculo axillari, folior. 3-4 brevior. involucri. Involucri folioli 2, profunde biloba, (sinu latô) plus minus coalita interdum, venosa, sinu aliquando in lobum folior. formâ simile product.

Cor. non visa.

Fructus juniores sessiles, 5-alato angulato, apice sepalis 5 lineari oblongis concavis obtusis magnis (æquantibus tubum) venoso-reticulatis coronatis, discoque epigyna 3-loculares, loculi 4-6 spermis. Semina (juniora) anatropa pendula, periparia subcollateralis, uno loculi cujusque tantum perfect. Raphe extrorsum.

Fruct. maturus involucri planato suffult. descreti subrotunda læves, glabri, baccati, calycis laciniis immulatis, coronat. sub 3-loculares. Semina pulpa immersa, fertilia læte ovata compressa, pendula, micropyle supera. Tegum. exter. pulpa adhær. crustac. crassiuscul. Interius tenuiss. memb. Albumen copiosum carnosum-oleosum vestiens. Embryo axilis,

albumine duplo circiter brevius. Radicula crassa supera. Cotyledones foliaceæ, planiusculæ? lanceolato-ovatæ.

HAB. Hindoo-Koosh Shingly bouldery ground about the Torrent, Upper Kaloo, alt. 11500 ft. In fruit in *Sep.* 1840.

Obs. The outer layer of the ovarium in the youngest state I have seen it, is separable, from the body, with which it appears to have no connection, only becoming continuous with the calycine laciniaë at their base. The body of the ovaria then presents 10 costæ, not very prominent, 5 opposite the sepals and continuous with their central veins, 5 alternate. The union of the placentæ in the axis appears slight, no particular ovulum appears to be fecundated, I have not been able to ascertain positively whether the position of the raphe relative to the placenta is due to a torsion of the funiculus.

This appears to be an undescribed genus, approaching so far as the characters in Endlicher's *Genera* go, to *Lonicera* and *Triosteum*. As however it approaches in habit somewhat to *Lonicera bracteata*, Royles *Illustr. t.* 53 and agrees tolerably with the character of *Lonicera, chamacerasus*. End. *Gen.* no. 3337. I have referred it to that genus, it may be necessary to look at the bractæ again,—particularly the fruit.

Carpella 2, secedentia pendulaque ex apicem, e basi fructus ortum ducentis accumbentia, complanata, alataque, disco centrale carnosio, baccato viride odoris aterimi.

Semen unicum ovale cuique carpello, medio affixum, parte baccata inclusum, parieti hujus exteriori approximatum.

Tegumentum tenue subobsoletum ex albumina secedens et cavitatem loculi quasi adnat.

Albumen carnosum forsitan ob immaturitatem.

Embryo axilis radicle longiuscula infera teres. Cotyledones planæ cordatæ foliaceæ. Plumula inconspicue.

2. *Pæderia*, Pl. CCCCLXXIX. Fig. IV.

Planta scandens volubilis.

Fructus cymosus paniculatus brunneo-castanea globosus lucidus, apice coronata calyce breviter 5-dentata, dentibus in fructu depressis siccus, calycis parietes tenuissimi liber!

Pericarpium baccatum liberum biloculare, pulpa gelatinosa diaphana extus virida.

Semen 1 cuique loculo plano convexum, introrsum leviter curvatum potius arcuatum vix plano-convexum sed menisci-forme apicem versus affixum.

Albumen corneum amplum. Embryo orthotropus axilis, directione albumis. Radicula brevis obtuse. Cotyledones planæ foliacei accumbentes. albæ rotundatæ basi profunde cordatæ. Fructus indehiscens, secus septam in hæmisphaeros 2, demum secedens. Plumula inconspicue.

HAB. ASSAM. Odorque præsertim fructus *Pæderiæ*, occurrit in sylvis ubique paulo infra Suddhya Negrigam usque : *Jan.* 21st, 1835.

PSYCHOTRIA.

Psychotria, Pl. CCCCLXXIX. Fig. II.

Fructus capitata, capitulis bracteatis in cymis terminalibus disposita baccata breviter stipitata. Baccæ ovates, coc-

cineæ læves, apice toro concolore, medio foveolato coronatæ, cæterum nudæ, calyces nempe limbo deciduo, biloculares, 2 spermæ.

Semen 1 cuique loculo erectum, plano convexum faciebus planis internis approximatis.

Tegumentum duplex, exterius fibrosum coriaceum fibris tenuibus irregulariter dispositis, interius cellulosum rubrum, inter albumen facie externa convexa, pluries et haud profundem intrans, secus fauci planam interiorem medium seminis versus profunde et in locis duabus intrans. Raphe fibrosa chalazaque inconspicue albumen corneum ruminatum.

Embryo orthotropus basi albuminis versus locatus hujus directione.

Cotyledones planæ foliaceæ, incumbentes serie faciebus latioribus seminis parallelæ.

Plumula inconspicua. Radicula longa teres apice conica.

HAB. Frutex. In sylvis per totam regionem. Upper Assam vulgatum occurrit. *Feb.* 1836.

The outer integument consists of at least 2 layers, owing to the contrary directions in which they pass and to which the irregular fibrous appearance is to be attributed; near its surface vast quantities of fascicled raphides occur.

It is well worthy of examination to ascertain whether the direction of the cotyledones is in all the 2-seeded species of Rubiaceæ, parallel to the broader faces of the seed, and whether, in the many seeded it is the reverse. In these last however the narrow borders may be the true faces.

EPITHINIA.

Epithiniæ sp. Pl. CCCCLXXVIII.

Arbuscula vel frutex, corona rotunda. Fol. longiuscule petiolatis obovato-rotundatis, obtusissimis, præcoriaceo-carnosis glaberrimis integerrimis margine sæpe voluto, venis secundariis paucis distinctiusculis. Stipulis interpetiol. ore integerrimis annuli in more coalit. basi gibbos.

Cymis axillaribus foliis brevioribus pluries dichotomis, florem dichotomum primaria scrotino, bracteis sub 0. Floribus parvis numerosis ex albo carneis.

Calycis tubus compressus elongatus sub 8-lineatus ultra ovarium in limbum minuti 4-dentat. membranac. product.

Cor. hypocraterif. 4-partita laciniis reflexis late ovatis, æstivatione leviter contort. throat very hairy, tubo calycis limbo duplo longiore.

Stam. fauci inserta, reflexo-patenta exserta filam. brevita. Anth. dorso affixæ subsagittatæ loculis pollinif. linearibus Pollen.?

Discus epigynus sub 8-lobus.

Stylus rubescens exsertus, apice incrassato-bilobum, lobis sub divergentibus interne stigmatosis.

Ovar. biloculare. Placenta loculi cujusque intrans *centralis* divergente bipart. ramulo supero ovulum erectum affigens, infero ovulum pendulum. Tegument connata? Raphe $\frac{1}{2}$ completa, apex nuclei hilum prope.

Fructus oblongo compresso 8-sulcato carinat. Epicarp. celluloso-spongiosum. Mesocarp. crasso in carinas product. album, indurat. Endocarp. osseum, vix separabili spontaneum in pyrenas duas, calycis limbo imulat.

Semina sæpe abortiva, situs et forma ovulorum, hæc erect, hoc pendulum. Tegument. membranac. tenue, hinc raphiger albumen carnosum, mediocre.

Embryo orthotropus albus (radicula longiuscula hilum versus epectans) Cotyledones planiusculo.

HAB. In Rhizophoreis Pulo Bissar. Circa Singapore vulgatam.

OBS. It certainly has stipules, but the usual lamina is nearly abortive.

Wight and Arnot have mistaken, at least the situation of the upper ovulum, and their description of the stigma is incorrect.

The fruit is scarcely drupaceous.

The radicle is not superior in the upper seed, in both quoad the seed and placenta it has the same direction.

1. Plant nat. size.
2. Apex of a branchlet, shewing the vernation and stipulation.
3. Bud just before expansion.
4. Portion of inflorescence.

11. Ovarium part of limb of calyx cut away to shew the lobed epigynous disk.
12. Long section of ovary shewing the peculiar placentation and direction of ovula.
13. One placenta removed.
14. Fruit.
15. Transverse section do.
16. Long section do.
17. Seed long section one cotyledon cut away.
18. Embryo.

IXORA.

Ixora decipiens.

Frutex, foliis oblongis. Inflorescentia thyrsoido-paniculata, paniculi trichotomi. Dentes calycinæ paullo post anthesin pallide rubri. Flores albi.

Cal. tubo brevi 4-dentat. dentibus erectis, postea deciduis.

Cor. tubo cylindrico calyce triplo longiore, limbo 4-fido, laciniis reflexis. Faux nuda.

Stam. 4 laciniis alternantia. Filam. fauci inserta, reflexa. Antheræ introrsæ, reflexæ, biloc. longit. dehiscent.

Stylus filiform longitudinis tubo, a basin usque ad medium parce pilosus. Stigmata 2.

Ovarium biloc. loculis 1-ovulatis, placenta axilis. Pericarp. baccat. globosum magnitudinis pisi. Semina plano-convexa, testa dura albumen carnosum. Punctum hili situm indicat. Cotyledones cordatæ planæ foliaceæ. Radicula longe hilum spectans acutis coriaceis integris.

Structure of the coats of the seed. External coat testa, is formed of loose cellular substance, almost horny of elongated cells, which have no determinate direction.

Endosperm, of elongated cellular tissue resembling woody fibre and running in a longitudinal direction, it is capable of being detached with tolerable facility. Pl. CCCCLXXIV. Fig. II. longitudinal section of the seed with a plan of its inner surface and view of the cotyledon and radicle. *March 31st, 1833.*

SPERMACOCE.

Spermacocæ sp.

Pubescentia hispida decumbent. ramis bicanaliculatis, foliis subsessilib. lanceolato-linearib. acutis cum mucrona, integris, stipulis multi-setosis, floribus in axillis congestis, albis.

Cal. tubo brevi dentibus 5, lanceolatis ciliatis mucronatis, demum conniventibus pilosus, sinubus acutis.

Cor. tubo gracili, calyces dentium longitudinis, limbo 4-partib. laciniis revolutis parce pilosa.

Stam. 4, longe exserta fauci inserta. Anth. albæ.

Stylus longus stamina æquans, stigma bicapitatum.

Ovarium biloculare, loculis 00 ovulatis, calyce connivente inclusum.

HAB. In umbrosis Madamaca : no. 232. *August, 1834.*

LECANANTHUS.

Suffrutex humilis vix uno pedalis. Caule basi forsan excepta 4-gona, angulis e stipulis decurrent magis acutis et elevatis ;

stipulæ membranaceæ magnæ oblongæ, infra medium centro carinato-alatæ. Fol. breve petiolatis ovato vel oblongo-lanceolata cuspidato-acuminata coriacea subtus albida 2 dariæ venæ arcuatæ.

Spicæ capituliform. axillares, livido-purpureæ horizontales, seu $\frac{1}{2}$ cernuæ; surrounded by a peltately attached, subseveral-lobed involucre, os calycem bilabiata et inæqualiter tubæform.

Cor. bilabiata tubo infundibul. calyce paullo longior. the upper lip *in depressed* segments narrower, conspicuous uncinato-carinate parallel.

Lower 3 diverging, reflexed carinato-uncinate at the summits or deorsum.

Cal. of flower bilabiate, lab. inferior subintegro, superior 3-dentato majore often nearly entire. Stam. inserted about the centre of the tube, which is papillous, or at the back of the anthers hairy.

Style pilose. Stigma of 2 recurved, stout green lobes.

Ovary 2-celled, cells multo-ovulate. Placenta intrant fleshy.

Anth. adnate sublanceolate bilocular longitud. dehiscent.

Epigynous disk small entire.

Stout brown hair-like processes in the axilla of leaves, arising from the inside and edges of two liguliform axillary processes, or from axils direct; they cohere to the stipula bases.

Involucre at first, when only the peripheral flowers are developed—is campanulate.

Young fruit 2-celled, few seeded, terminated by the trumped-mouthed calyx.

Seeds angular, compressed, very few compared with the ovula.

HAB. Malacca. In sylvis densis Verrupha, called Aloor Gagah.

Obs. I imagine this approaches to *Ophiorhiza*, although according to DeCand. it would be *Gardeniaceae*, and *Sarcocephalina*. Flowers scarcely bracteolate, here and there setæ

like the axillary ones, only one expanded flower seen; this same when put in water for preservation during the night lost its bilabiate form, and became as nearly as possible regular, venation ordinary.

Evidently *Lecananthus* of Jack and agreeing with his *L. rubescens*, except in the regular corolla and smooth ovary.

Jack's generic character is not so good as ordinary.

Cal. tubulosus ore tubæformi bilabiato. Cor. valvata, bilabiata, laciniis subæqualibus, tubo infundibulif. Stam. medio tubo inserta, subsessilia inclusa. Ovarium bilocule, *placentis intrantibus carnosis*, (septo quasi affixis) ovula 00. Stigmata 2, crassa, oblonga, subexserta.

It has nothing to do with *Nauclea* whatever; the ovarium is, while the tube of the calyx is beyond the limb, livid purple, the last is pubescent inside. Calyx well developed before the corolla.

Surrounding the internode *base* immediately next to inflorescence, is a sheath, the sheath of the gemma.

Rubiaceæ Pl. CCCCLXXIX. Fig. I.

Fructus in cymos terminales aggregatos dense congesti, baccat.

Baccæ obovatæ vel obovato-pyriformes, spongiosæ albi subdiaphanæ apice profunde foveolatæ. Calycisque dentis brunneis lanceolatis acuminatis connovente imbricatis coronatæ pseudo 4-loculares. Calycis parietis nempe a pericarpio secedentis nisi secus lineam septorum et utrinque placentis opposito.

Pericarpium biloculare membranaceum tenue, septis membranaceis discretis. Placentæ carnosæ stipitatæ his oppositæ.

Semina 00, complanata irregulariter 4-angula brunneæ pulchre reticulata.

Tegumenta duplex utrinque adhærens exterius coriaceo-membranacea tenue e reticulatum brunneum, interius tenuiss. membranaceum album, albumen corneum.

Embryo obliquus hili latus unum oblique spectans. Radicula conica infera, cotyledones accumbentes seu faciebus angustiorib. seminis opposit. plano-convexæ. Plumula inconspicua.

Frutex 3-4 pedalis.

HAB. In sylvis, per totam regionem. Upper Assam vulgatum occurrit.

SCÆVOLEÆ.

Scævola Taccada, Roxb.

Suffruticosa ramulis crassus, foliis alternis sessilibus obovatis carnosus læte viridibus, apices versus repando-dentat. sinibus brunneis supra nitidis. Cymis florum axillaribus paucifloribus, foliis multo breviorib. floribus majusculis albis demum brunneo-ochroleucis marginibus laciniarum basin versus et nervo medii tubique fissi, rubro-brunneis.

Pet. sinuato-repanda demissius ciliato-laciniat.

Anth. membrana terminat. Indusium e pilis albis.

Ovarium calycis dentibus coronat. biloculare, loculis 1-ovulatis. ovulis erectis pericarp. drupaceum.

HAB. Mergue. In littorib. arenosis. Ins. parvæ prope ostium-lumen. Palar copiosa: *Oct.* 1834.—*Nov.* 1833.

It forms patches or belts of the most beautiful green I have ever seen.

STYLIDACEÆ.

STYLIDIUM.

Stylidium Brunonis Gr.

Stylidium, caulibus basin versus incrassatus, foliis subrosaceis, spicis ramosis, floribus distantibus, foliis cellulosis inconspicue 3-nerviis.

Cal. bilabiat. 5-partitus $\frac{2}{3}$ labiis sublateralibus nec vere postico antico, lab. 2-fido sinistrorsum, 3-fido dextrorsum.

Cor. tubo brevi, limbo irregulariter 5-fido, lobo postico reflexo dentiforme, lateralia intermedia subtruncata, 2-inferiora majora, biloba.

Stigma papillosum. Sem. ovat. testa cellulosa.

HAB. Mergue.

SPHENOCLEACEÆ.

SPHENOCLEA.

Sphenocleæ sp.

A succulent marshy annual with alternate exstipulate leaves, venation ordinary.

Flowers arranged in dense terminal capitula, sessile, tribracteate.

Cal. adherent 5-lobed, imbricate quincunciate margins membranaceous, persistent unchanged.

Corolla small, 5-partite, laciniae inflexed imbricate in æstivation; venation simple, one central to each lacinia ending within the apex.

Stam. 5 opposite the sepals inserted into the tube towards its base, e vascular. Filaments short.

Anthers 2-locular, longitudinal, opening attached to the apex of the filament. Pollen smooth with 3 pores.

Ovar. entirely adhærent, 2-celled, ovules 00 antitropal.

Capsule crowned with sepals, which almost entirely cover its convex larger disc, style deciduous, 2-celled, seeds 00 testa shortly echinate membranaceo-coriaceous.

Albumen none. Embryo orthotropous.

Testa externally cellular, immersed bulging out into cones each of which is traversed from base to apex on both sides by a fibre.

The embryo separates with its integument probably the embryonary sac, this is furnished with a mammilliform process at either end, that next the hilum being the largest, the other represents its base, no raphe exists.

CAMPANULACEÆ.

CYCLOCODON.

Cyclocodon distans Gr. Pl. CCCCLXXXI. Fig. I.

Caule subscandent ramoso rubro, articulis paulo incrassatis, fol. opposita breve petiolata lanceolata valde acuminata, mucronata serrata, 1-venia, venulis secundariis subarcuatis purpureo sæpe tinctis. Ramis apice trichotomis ramulis dichotomis, flore in furca solitario, in apicibus ramulor. sæpius 3-natim aggregatis. Pedicellis filiformibus rubris floribus albis carneo-tinctis.

Involucra 4-phyllum, patenti-reflexum, foliolis linearibus dentatis, interdum oblique insertis, verticillis nempe non formantibus.

Flos breve pedicellatus, pedicello fructifero parum elongato.

Calyx? ovario omnino adnatus truncatus obsolitus.

Cor. rotata epigyna 4-partita, laciniis cordatis acutiusculis 1-venis venulosis, æstivatione angulato valvata.

Stam. 4 epigyna laciniis corollinis alternantia, filam basi lata plana, filiformia demum marcescentia. Anth. oblongæ bases versus affixæ, biloculares introrsæ et longitudinaliter dehiscent. Pollen globosum minute hispidum, ovarii apex depressus concavus.

Stylus filiformis, pilosus, stigma 4-lobum lobus papillosus demum recurvis.

Ovarium adnatum omnino inferum 4-loculare loculis cruciali dispositis. Placentis carnosis bipartitis apicis versus liberis.

Ovula 00, oblonga foramen hilum prope. Tegumenta distincta 0.

Fructus capsularis subglobosus, apice depressus corollaque genitalibusque marcescent. coronat. 8-sulcatus, sulcis septis respondentibus, profundioribus, 4-loc. Placentæ 4 carnosofungosæ, loculos ex maxime parte replentes, apices versus liberæ, medio sulcatæ vix bipartitæ. Semina 00 valde compressa, subovalia, brunnea nitida. Tegument. simplex fragile, minute areolatum. Albumen carnosum farinaceum copiosum. Embryo minutiss. in axi albuminis. Radicula hilum versus spectans. Cotyledones parvæ, their faces corresponding to the greater diameter of the seed.

Septis ovarii petalis alternantibus, placentis carnosis succus lacteus parvus.

HAB. Khasyah Mountains. In sylvis Churra : *Oct. 16th*, 1835.

Obs. The above description is probably wrong, as the involucre is most likely calyx, although the fact of the tube of the corolla being adnate to the ovary, while the calyx is free, is an anomaly of extremely rare occurrence.

In my Mergue species, *C. adnata*, Gr. the involucre is adnate to the base of the ovary.

CAMPANULA.

1. *Campanulæ* sp.

Herba 4 uncialis annua in arenosis proveniens, fol. sessilia linearia obtusiuscula subdentata, flores pauci longiusculi pedunculati.

Calycis tubus lævis obconicus.

Delvi apud Meinkhoon : *March 25th*, 1837.

CODONOPSIS.

1. *Codonopsis albiflora*.

Sub scandens erectave herbacea, caulibus ramisque teretibus petiolis brevibus basi dilatatis, fol. sæpissime opposita aliquando subopposita, lanceolato-acuminata dentato-serrata, basi subcordata, tenera floribus terminalibus et ex axillis folior. 2 summorum solitariis majusculis albis pedicellis elongatis, foliis brevior. infra florem sed supra medium 2 bracteata, bracteis linearibus dentatis, foliaceis sæpius oppositis.

Cal. tubo sub o basi planus 4-5 partitus laciniis linearib. elongatis serratis, bracteis consimilibus, æstivatio aperta.

Cor. subcampanulata. tubo brevi viridescens ovario adnato ! 4-5 partita, laciniis subcordatis vel late ovatis, acutis æstivatione valvatis *marginibus prominentibus*.

Stam. 4-5 epigyna libera, laciniis corollæ alternant. inclusa, filam. complanata basibus dilatat. Anth. erectæ subsagittat. bilocul ælongit. dehiscentes *introrsæ*. Pollen rotundat. hispidulum album.

Stylus 1 brevis, cylindricus apice versus pilifer. Stigmata 5-6 oblonga crassa patente erecta.

Ovar. 5-6 locale vel loculi tot quot styli, loculis 00 ovulatis, ovulis placentis intrantibus carnosiss affixis, foramen hilum prope.

Fructus capsularis calyce laciniisque persistentibus stipatis, laciniis corollinis subdeciduis ideoque quasi truncatus videtur filamenta bases persistenti inflexæ, stylo apiculato 5-6 locale.

Placentæ albæ carnosæ si 5, *bifidæ*, sem. 00, minuta. Testa brunnea pulchre reticulata, albumen farinac. Embryo minutus axillis orthotrop. Semin. immatur. vidi.

HAB. Mergue. In cleared ground about Banlaw and Yengboo: no. 1013, Feb. 1835.

Obs. The limits of the calyx are well defined in the fruit by a line passing between the permanent laciniæ, hence the tube of the corolla is either adhærent to the ovary, although this is not demonstrable, or else the corolla is epigynous. In the bud however, the middle nervure is distinctly prolonged to the calyx, and the adherent part is so similar to the free, that I have but little doubt that such is the case. The existence of two layers is not demonstrable by a transverse section, if such is the case it is a *singular* instance of an ovarium united both to the calyx and corolla, to the latter in a much greater degree.

2. *Codonopsis* sp.

Scandens volubilis, foliis canis cordato-ovatis basi subreniformibus mollibus e rugosulis, fructibus axillaribus breve pedunculatis nutantibus. Pedunculis rubris basin versus, apice cæruleo-purpureis.

Calyx reflexus, laciniis foliaceis lanceolato-oblongis minute venulosis purpureis, depress. basi cæruleo purpureo, fructibus cujus basi calyx adnatus globosus truncatus apice cicatric. corollæ 5-augulatæ notat. et areolata, areola 5-angularia superficie saturato purpureo cæruleo, cæcio areola cujus majore magis rubescent. nitida, cicatrices stamina angulis

alternantibus, basis styli ex medio areolæ prominula conum referens.

Fructus pseudo-baccatus pericarpium parietes tenues carnosus, 5-locularis. Placentæ maximæ carnosæ transversæ, loculos fere replentes, septis axin versus distantibus nec approximatis, faciebus intrantibus internis basi fructus versus papillosis.

Semina 00 minuta, tota superficiei placentarum bases versus interne tantum excepte, ovalia minute punctulata foveolato more, pilo brevissim. apicule filiforme, testa subcoriacea crassiusculi subsimplex.

Albumen carnosum a tripliusculum. Embryo axiliis. Radicula longiuscula subulato-conica hilum spectans. Cotyledones carnosæ minutæ plano-convexiusculæ.

HAB. Khasyah Mountains Bogapanee : Nov. 5th, 1835.

3. *Codonopsis* sp. Pl. CCCCLXXXII.

Stigma terminal. punctiforme, canal. stigmat. simplex, *i. e.* termin. ovula pauca, 5-7 erecta, tegmentis cum nucleo concretis, foramine inconspicuo prope hilum, et extus spectans, raphe ramosa.

Fecundatio præcocio, stylus nempe exalbastro cito exseritur et longe ante stam. dehiscent.

The corolla is slight monopetalous, the lines marking the separation of the sepals extending below the sinuses nearly to the base of the tube, and there diverging from each other, so that it is entirely bound together by the sterile stamina, which extend outside to the base of the tube. The relative situation of the sterile and barren stamina appears viewing the corolla unopened to be the reverse of what it should be, but when the corolla is laid open, there is a certain prominence down the tube, along the course of the filaments, that leads me to believe that their exterior situation is due to the adhesion being carried up beyond its usual limits. The sterile stamina are vascular.

There would appear to be a tendency in this plant to rupture of the ovary. In the two instances I have seen, and in which the rupture, judging from the margins, and the width of the rupture, was of considerable standing; the young seed was as perfect in its development, as in the normal state. This rupture from the appearance of the margins is scarcely to be attributed to insects.

The embryonary sac is a large fleshy transparent sac, curved in the direction of the seed, its surface is undulated,—the first steps to its rumination, so that in

this instance the membrane inflected into the albumen will be partly at least nucleary. The stalk of the embryo is exceedingly large, the largest I have met with, it is worthy of remark that, at its apex it is very laxly cellular, the tissue gradually becoming more condensed as it approaches the embryo, still no part of the radicle is formed from it.

This is obviously a transition genus, between *Myrsineæ* and *Sapotaceæ*, with a preponderation perhaps of characters in favour of the former where it is placed by Dr. Falconer. The relative affinity it has with the two above orders may be decided in favor of *Myrsineæ*, on account of its habit and inflorescence, which is like that of *Myrsinea*. It probably comes close to *Jacquinia*.

The inflexion of the filament is a curious character, the anthers however return to their usual direction, (is this the case in *Melastomaceæ*?)

The protrusion of the style, at so early a period is unusual, it is not united with a correspondingly early dehiscence of the anthers, but it is perhaps? associated with the late expansion of the corolla, which forms a tube round the style.

It would appear that fecundation is unusual, although fruit is produced in immense quantities, but their quantity compared with that of the flowers is extremely small, and seldom more than 2 young fruits are to be found in an axilla.

The order *Myrsineæ* appears to me unnatural, nor can I think otherwise, viewing such genera as *Ardisia* united with *Myrsinea*, but I know few of the plant it contains.

The calyx is entirely that of *Sapotææ*.

Cal. 5 sepalus. Cor. subrotata, laciniis reflexis, stam. sterilia 5, fertilia 5, lacinia basibus insert. æstivation imbricat. filam. inflex. ovar. *unilocul.* placenta sub 0. Ovulis erectis, anatropis.

COCULUS.

1. *Cocculus convolvulaceus*.

Volubilis glaber. caulis teres, spiraliter lineatus.

Folia cordata, aliquando cordato-rotunda, acuminata cuspidatis integerr. basi 7-nervia, subtus glauca et reticulata. Petioli $\frac{1}{2}$ pollicis longi, basi latiores, et sublobati.

Inflorescentia fasciculato-racemosa. Racemis axillares basi articulati foliis longiores.

Flores in fasciculis 4-5 florum dispositi ad basin cujusque fasciculi bractea linearis decidua. Flores lutei, ingrati odoris.

Sepala 3 ovato-lanceolata ima basi discreta.

Pet. 3 sepalis, 4 duplo majora, et iis alterna, oblonga patentia marginibus recurvis.

Stamina 6 hypogyna, biserialia, seriei externa sepalis, interna petalis opposita. Filamenta clavata. Antheræ extrorsæ, bilocul. longitudin. dehiscentes. Squama stipitata, limbo rotundo-obovata, filamenta cujusque externe basin suffultiens.

Rudiment fæm. vel nullam vel imperfectum, concavo-convexum latus concavum ovulum imperfectum gerens.

CHAR. SPECIF. C. foliis cordatis, acuminato cuspidatis 7-nerviis utrinque glabris, subtus glaucis reticulatisque pedunculis masculis axillaribus, subcompositis, folio longioribus.

Obs. It is more agreeable to the laws of organisation to refer the outer series to the calyx, the inner to the corolla.

I think the fact of the stamens being distinctly in two series, (and consequently their corresponding squamæ or pet. D. C. being so) disproves the idea of the squamæ being petals. Petals are usually situated between the calyx and the stamina, these scales are thus arranged—3 scales, 3 stamens. Taking them for petals, we have the following anomalous arrangement. A calyx of 6 sepals situated on two distinct planes, 3 petals, with three stamens and 3 petals, 3 stamens. If they are petals the stamina do not appear to be hypogynous, but periginous, universally separating with the scales.

I observed an imperfect development of the ovarium in some male flowers.

2. *Cocculus nudiflorus*.

Caulib. scandent. volubil. carnosus. Fol. 0. Racemis ex axillis folior. lapsor. 3-4 uncial. multifloris erectis. Pedicellis basi bracteatis, floribus majusculis fusco-viridibus.

Sepal. 3 minuti, ovati. Pet. 3 iis alternant. multo majore, patentia. Squamæ 6 hypogyna petaloideæ quorum 3 exteriore majore, sepalis opposita, 2 interior minore petalis marginibus basin versus involutis.

Rud. stam. 6, hypogyna, breviss. setacea, squamis opposita, apicibus obtuse conicis.

Carpella 3 distincta, toro dilatato elevato insidentia, sepalis opposita.

Stylus crassus breviss. Stigma subreniforme repandum, 1-loculare, 1-ovulat. ovula pendulo ab apicem locule versus, foramen hilum prope super. Tegument. ovulisimplex.

HAB. In sepib. Mergue: *March*, 1835. Masem legi apud Motow sed nex exminandum: *Feb.* 1835.

Obs. The stem presents two separate systems of wood, the outer fibrous disposed in arches, the ends of which communicate one with the other, the fibro vascular or inner, deposited in irregular bundles, near the pith; these bundles are quite distinct. Interposed between the two formations, is lax uncolor-

ed tissue. The whole tissue abounds in amylaceous granules of large size. The vessels are very large and as they are in *Plytocrena*.

3. *Cocculus villosus*.

Fruticosa dioica brunneo-pubescens. Ramis scandentibus, foliis alternis exstipulatis, petiolatis, elliptico-ovatis mucronatis, integris ciliatis reticulatis utrinque brunneo pubescentib. floribus in axillis aggregatis solitariis internisve in pedicellis, subnulant. inconspicuis viridibus.

Squamulæ hypog. 6 cuneato obovato subintegra, medio sulcatæ.

Stam. totidem hypog. squamulis opposita, biserialia, serie exter. sepalis opposita, interna petalis opposita, filam brevia subclavata connectivum carnosum. Anth. bilocul. loculis discretis medium versus dehiscent. Pollen ovatum leve hinc sulcatum. Æstivatio corollæ valvata.

HAB. In sylvis. Mergue: Sept. 1834.

CESSAMPELOS.

In my remarks on the collection of Plants made at Sudyah, I pointed out under Menispermæ, the variation in site of the placentary suture in *Cissampelos* from that which usually obtains. It is scarcely necessary for me to explain that it is a law to which no real exception is I believe known, that this suture is invariably next the axis.

This is most evident in those ovaria, which are formed by the coalition of several carpellary leaves, but although less evident, is as strictly true in those cases, in which the carpellary leaf, from whatever cause this may originate, stands alone. In such a case, its situation would be thus: see explanatory sketch, Pl. CCCCLXXXVI. Fig. II.

Indeed were it not so in case of additional carpella, being formed, it is at once evident, that the placentæ of these would have no tendency to meet in the centre, they would instead of all being directed towards the axis, be all directed towards the circumference. Upon these grounds the supposition, that in the plant referred to, the flowers produced from the axillæ of each bracte, form part and parcel of a single flower, is untenable, as will be at once seen by looking at the explanatory sketch, which represents the structure of *Clypea*. Pl. CCCCLXXXVI. Fig. II.

The supposition otherwise, considering that the female flowers are generally aggregated by fours, corresponding to the quaternary structure of the males, seemed not improbable.

But the true explanation has been offered to me by my valued friend Dr. Wight, and this is borne out by the consideration of the stigmata, to which I ought to have paid more attention. The stigmata of this genus appear to be invariably three, and we may take this as a proof that the ovary is solitary by abortion, of the three stigmata, the central one is external with reference to the axis, it is solitary by the abortion of the two lateral ovaries.

Granting these to become developed, the situation of the placenta will be natural: see sketch, *b* which points out what would be the situation of the placentæ of the lateral ovaries. Corresponding to this is the suppression of $\frac{2}{3}$, or generally $\frac{3}{4}$ of the parts entering into the composition of the Perianth.

1. *Cissampelos capitata* Gr.

Suffrutex volubilis pubescentia crispata præsertim folia subtus sublanata.

Caulis viridescens. Fol. peltata oblique cordato-ovata obtuse acuminata cum mucrone, ambitu deltoidea, subcoriacea integra, basi 9-venia, cæterum reticulata.

Petioluis uncialis biuncialisve teres axillæ gemmiferæ tan-

tum vel gemmiferæ floriferæque, gemma semper externa. Umbella petiolo brevior, simplex vel composita, radii inæquales, pedunculo breviores, basi bractea lineari suffulta centrale excepto.

Flores capitata, plures in quolibet capitulo, quorum centrali majora præcocioreque, sessiles, minute inconspicui, viridescentes, exteriores prius florentes, sæpissime nudi, irregulariter evoluti normaliter ternarium.

Sepala normaliter 3, spathulato-obovata pubescentia.

Petala totidem conformia sed majora.

Glandulæ 3 discretæ rotundato-cuneatæ carnosæ, glabræ, virides sepalis oppositæ.

Columna staminum petala subæquans cylindræa, apice dilatato plano. Antheræ 3, transverse circa caput columnæ sitæ, petalis oppositæ? transverse dehiscentes, ad anthesin una septis obsoletis confluentes, initio 4-locellatæ?

Pollen album, rotundato-angulatum læve.

HAB. Upper Assam. Suddyah in sylvis: *May 26th*, 1836.

OBS. Marem tantum vidi. Columnæ vasorum fasciculus unicus. Glandulæ mediatenus 1-veniæ. De situ staminum dubito judicare vix possibile est ob septa obsoletissime sed ob analogiam conjicio petalis opposita esse, ideoque glandulis alternantur. Sepala petala, et glandulæ sæpe numero variæ. G. sæpissime ternæ.

C. capitata, foliis peltatis cordato-ovatis basi 9-venis, capitulis florum umbellatis, glandulis tribus.

2. *Cissampelos* sp. Pl. CCCCXCVII. Fig. III.

The female flowers consist of invariably of 4 ovaries, seated somewhat obliquely on the apices of as many pedicells. Their only envelope consists of a double scale, which is always situated externally, the inner being smaller and more rounded.

The usual explanation of this is I fancy that the flowers are quaternarily aggregate, the perianth of each being re-

duced to one sepal and one petal which is from its situation most likely a transformed stamen. There can be no doubt that both these answer to parts of the female perianth. The outer scale being obviously a sepal, the inner a part of the cup-shaped body, which from the alternation of the stamens with the sepals cannot be petals, but most probably results from a modification of the stamina. This is too perhaps the most natural way; but the occasional occurrence in the order of several carpella suggests an idea as to the *composition* of the flowers of Cissampelos. In this case we shall have 4 sepals, and 4 scales, and 4 ovaries.

The greatest arguments against this are the invariable greater development of the 2 posticous ovaria and the separation of the pedicel, which last seems to me nearly conclusive, the plurality of stigmata.

Those in its favour are the invariable quaternary aggregation of the flowers, and the situation of the scales, which seem never to be developed next the axis.

All these fine speculations are knocked on the head by the fact that the ventral suture is not next the axis. The first view is therefore the correct one.

Ovaria pilosa postica gibba, convexa sutura ventrali antica sita, 1-locularia, biovulata an semper ovula collateralia subantitropa, foramen superum, stylus cylindraceus, brevis, stigmata subtria, simplicia.

Sepalum unicum, anticum externumve pilosum, late obovatum.

Squamula subreniformis, huic opposita, carnosaevasculosa.

After fecundation the ovarium suddenly enlarges and alters its shape, becoming as it were curved on itself, the chief cause seems to be the elongation of the placenta, the style and pedicel are at length brought close together.

It is hardened somewhat by the time the embryo has appeared, its sac which previously existed soon disappearing.

The cotyledons at least in their very young state are opposite, the great transverse diameter or broader sides of the carpellum.

3. *Cissampelos convolvulacea* var. Pl. CCCCXCVI. Fig. II.

Caule ligneo gracile volubili pubescente, pubescens cana. Fol. petiolata reniformi-orbicularia cordatave late emarginata, pubescente, basi palmatim 5-nervia, quorum intermedia bifurcata medium infra. Paginæ aliter venulis reticulatim anastomosantibus occupatur centralis in mucronem excurrit. Petiolis filiformibus teretibus.

Paniculis terminalibus axillaribusque partialibus subcymosis, filiformibus, gracillimis villosis, floribus herbaceis minutissimis. Alabastra subglobosa æstivatione imbricata.

Sepala 4 breviter unguiculata limbo, subdeltoideo cordato, integro crenulatove obtuso, dorso villosis venulis reticulata.

Discus cyathiformis parum profundum ore subintegro carnosus centrum floris occupat.

Stam. monadelphæ, columna brevis cylindræa apice pelata. Antheræ 4 interdum plus minus coalitæ, circa apicem columnæ transverse dispositæ, sepalis alternantes transverse dispositæ, sepalis alternantes, transverse dehiscentes et per diametrum longiorem.

Pollen album læve, ovatum, medio sulcatum.

Rud. fœm. 0.

HAB. Upper Assam. Suddyah in sylvis: *January 8th, 1836.*

Vix dubito quin apetala sit et urceolosa aboriginem ducat. ut patet ex analogia et structura carnosæ cellulosa? urceola.

The structure of the stem is remarkable enough, the centre is occupied by the pith which is green and from which several wedge-shaped broad rays radiate, these are green and again coalesce towards the circumference forming the integument or bark? The spaces existing between these rays are wedge-shaped and interiorly, and throughout their great-

er part are occupied by vascular tissue, consisting of large cells punctuated and placed end to end, and surrounded by dotted fibres. This stem is truncate on its outer edge. Immediately adjoining this is a mass of lax cellular tissue brown along its outer margin, which may have a different structure. There is still a small place left between this brown outwardly curved line and the mass formed by the coalescence of the rays, this is occupied by a small mass of woody fibre. I have recognised this curious structure in others of this tribe.

LOPHOPHYLLUM Nov. Gen.

Lophophyllum bicristata Gr. Pl. CCCCXCI. Itinerary Notes, p. 165, no. 854.

1. Female flowers viewed in different directions.
2. One of the sepals viewed from within.
3. Do. with the ovary ; this has no regular situation compared with the sepals, although it usually alternates with them, and as the sepals are usually right and left, one of the edges of the ovary is usually next the axis.
4. Pedicelli, two lateral cicatrices are those of the sepals, the terminal, of the ovary.
5. Abortive ovary, resembling much one of the sepals.
6. Oblique transverse section.
7. Pistillum.
8. Ovulum.
9. Pistillum.
10. Pistillum after fecundation, one sepal remains.
11. Ovulum of do., this represents I think the nucleus, the outer coat, distinct before fecundation having become intimately united to the wall of the cell ; but on this point I require more observations.
12. Pistillum more advance.

13. Do. its longit. section, if the above idea be right the inner smooth subdiaphanous portion is testa.
14. Do. more advanced, nucleus? much curved, its cavity very distinct, no embryonary sac as yet formed.

HAB. Bootan.

OBS. Allied to *Cissampelos*, but distinct by the binary sepals (each with a cuculate bracte) and single ovarium.

13. Long section of seed through the greater diameter, or opposite the raphe.
14. Embryo, raphal face of.
15. Do. dorsum.
16. Do. one cotyledon removed, shewing that they are opposite in their extention, and that their partial correspondence is owing to the obliquity of their inner margins.
17. Young embryo.
18. Do. viewed edge-ways.

HAB. Upper Assam. Suddyah in sylvis: *August 26th*, 1836.

4. *Menispermea*, Pl. CCCCLXXXVI. Fig. III.

Suffrutex scandens, foliis alternis, oblongo-lanceolatis, breviter cuspidatis, integris subcoriaceis supra lucidis, paulo basin supra 3-venis, v. secundariæ distinctæ paucæ, pagina cæterum reticulata. Inflorescentia ut patet e fructus dispositione paniculata.

Fructus compositus vel abortione simplex in pedunculo $\frac{1}{2}$ unciali utrinque incrassato, ovalis vel ovali-ellipticus viridis lævis, ovi *pidgeon* magnitudine, subsessilis apice depressus ad situm styli basis, secus faciem interna quoad axin, longitudi-

naliter lineatus, succus viscosus vel potius mucilaginosus, odor forte. Pericarp carnosum demum baccatum? Endocarpio albo membranaceo. 1-loculare, 1-spermum. Semen magnum, cavitat. pericarpium conforme, eoque secus lacturam ventralem affixum, cochleiforme, hilo nempe profunde excavato, albumen copiosum albumen carnosum superne hili apicem versus papilla obsoleta notatum. Tegumenta tenuissimum, facile non delegendum. Embryo inversus in axi albuminis. Radicula supera, brevissima. Cotyledones maximæ planæ foliacea oblongæ basi profunde cordatæ, stipatatæ. Plumula inconspicua cotyledones curvatum hippocrepidi-formem albuminis sequuntur.

Cotyledones nec parallelæ sed mutuo oblique sitæ secus marginem internos irregulares, tantum cordatæ, lateri exteriori vel potius auriculatæ.

HAB. Upper Assam. In sylvis Kujooque Thea indigena invenitur: *Jan. 17th*, 1836.

Of this I have examined 2 fruits, but I should like to determine which cotyledon is external and indeed more of their structure. I have little hesitation in referring it to *Menispermæ* from which it chiefly differs in the large size of the cotyledons, and in the position of the radicle; but the foramen in the ovulum may be inferior.

5. *Menispermæ*, Pl. CCCCXCIV. Fig. I.

Frutex tenuis volubilis scandens, breviter pubescens.

Fol. reniformia, vel cordata obtusissime vel acuta olim acuminata etiam subemarginata mucronata obsolete peltata, basi peltata 7-venia, supra sublucida, infra albida, interveniis minute reticulatis.

Petiolis basi subarticulatis, teretes diametr. transvers. folii majoremque vix æquantes.

Cymis paniculatis axillaribus, aggregatis ideoque summis upra axillaribus, petiolos subæquantibus ramis divaricatis ramulis paucifloris, flore terminali prius evoluto, ferrugineo pubescentibus.

Flores masculi minuti, viridescenti lutei basi 1-bracteolati. Sepala 3-minutissima, irregularia linearia spathulatave.

Petala (vel series interior perianth) 3-obovata unguiculata, lutescentia, parce pubescentia.

Squamæ 6, biseriatæ, seriei exteriori sepalis opposita pauloque majora, interiori petalis ovata concava marginibus nempe involutis.

Stamina 5, hypogyna squamis opposita, eodem more biseriata. Filamenta distincta basi connata filiformia valde crassa, apices versus extrorsum curvata. Antheræ terminales erectæ basi affixæ, biloculares longitud. lateraliter dehiscentes brunnescentes extrorsæ. Pollen lanceolatum hinc sulcatum, sulco uno pluri. Rud. fæminei ne minimum quidem.

Cuticula e cellulis sinuosis, his paginæ superioris estomatosæ majoribus.

Anatomia. Caulis, medulla laxa, periphæria versus arctior. Radiis medullaris magnis viridescens cum cortice continuus. Vasa spiralia medullam ambiunt. Systema vasculosa cæterum e cellulis punctatis mutuo applicitis end to end, circumdatis fibris punctatis. Vasa centrum versus multo majora, ideoque fibræ multo pauciores, forma systematis hujus partes plerumque obcuneiforme.

Spatia reliqua arcuum radiis medullaris peripherice convexorum occupatur tela cellulosa laxa distinctissima e cellulis quadratis.

Systema fibrosa densum e fibris impunctatis applicitur arcu cuique peripherice, hujus partes componentes minimæ sunt.

Cortex interspatia arcuum radiorum medullarium non omnino implet.

HAB. ASSAM. In sylvis Cheikwar: *April 8th*, 1836.

PHYTOCRENE.

1. *Phytocrene stylocarpa*, Gr. Pl. CCCCLXXXIX.

Fructus aggregatus interdum capitis humanifere magnitudine, breve pedunculatus et quasi sessilis in ramo.

Drupæ plurimæ oblongæ, subparallelogrammicæ sulcato-angulatæ, sæpius compressæ, $2\frac{1}{2}$ unc. long. $1-1\frac{1}{2}$ lat. apice depresso, stylum proficiente basi cincta et sæpe cuspidata, perigonio albido membranaceo ad medium 4-partito.

Superficies, pilis deflexis acutissimis rigidis e basi oblonga pilos alios plures multo minores gerente ortum ducentibus et terminantibus. Substantia, dimidium superius solidum, firmum, fibris percursum inferius, exterior pars tenue firma, intus carnosafibrosa, putamini adhærens.

Putamen quasi pendulum, ovatum vel lanceolatum, sæpius compressum, pulpa gelatinosa vestitum basi excepto qua abrasum, osseum, crassum, fragile, scrobiculatum, utrinque ad apicem emarginatum, apicis quasi *hili bi-ocellatum*, sæpe hilum versus utrinque lineis 2 parum prominulis cito evanidis notatum, brunneum, intus albido-ochroleucum et papillis subhæmisphæricis rugosum.

Semen solitarium (nondum licuit ovulum alterum detegere) pendulum conforme. Tegumentum tenuissimum membranaceum, raphe $1\frac{1}{2}$ completa lineata, sæpe e maxima parte albumine obtecta.

Albumen e lobulis innumeris conflatum, carnosoleosum cæseinum, odoris ingrate, lutescens. Embryonis cotyledones sigmoideo duplo flexæ, foliaceæ, ochroleucæ. Radicula brevis, magna, supera.

The putamen might easily be taken for the seed, for the pulp, except at the base, separates apparently, evenly and smoothly; but the raphe on the membrane covering the tegument shews the real nature, setting aside observations on the young fruits.

Of two specimens one had the drupes more elongated and

less compressed, the others a good deal compressed and about ovate.

The albumen of these presented generally the lobes in partial state of separation, and then much more rounded, indeed they appeared as though they were stuck on the outer faces of the cotyledons in a single row, in these too, the integument was often interrupted in continuity, and occasionally nearly floccose.

The margins of the cotyledons are often not covered with albumen; the albumen adheres to the surface.

In the ovate seeds, the integument seems to dip here and there under the albumen, but this is due to the form of the seed, and only occurs along the lines of flexure.

The structure of the albumen is like that of the Olacineous Mergue plant; but the tegument in that is highly vascular, and the inflexion really takes place to a great extent.

1. Fruit natural size.
2. Drupe with the perianth at the base.
- 2a. Ditto without the perianth.
3. Long section, the outer part of the seminiferous part pulled away from the pulp, not cut.
4. Putamen detached.
5. One of the more elongated ditto.
6. Putamen, pulp rubbed off.
7. Ditto laid open to expose the seed.
8. Long section of seed.
9. Transverse.
10. One, often more elongate seeds.
11. Transverse section of the same.

HAB. Penang.

Phytocrene stylocarpa? semina, Pl. CCCCLXXXIX.
Fig. II.

Pyrena Putamen received in June 1843 from Dr. Cantor.

Ovatum compressum versus hilum or attachment, where it

is distinctly two edged, and on the broad veiws presents 2 or 3 costæ, the surface is punctulate the seed loose side.

The putamen is thick and long, and very hard outside, inside irregular roundish elevations (corresponding to puncta?) Seed of the same shape attached to the end of the putamen on which the mark of attachment is, on one side is an irregular nearly closed up foveola along one of the broad faces. The albumen is lobed, the lobes are so pressed together as to appear mere areola, and almost naked, but there are traces of a very fine integument which passes probably between the lobes.

2. *Phytocrene macrocarpa* Gr. Pls. CCCCLXXXVII, and Pl. CCCCLXXXVIII.

Frutex scandens robustus, caule præsertim in part. novel. aculeato, aculei conico sine ordine. P. novellæ, sicut ramuli ferrugineo-tomentosa, tomento *strigis* immixto.

Fol. alterna, exstipulata Menispermaceo-Artocarpina.

Petioli teretes, (of old leaves immersed at the base into a deep foveola in the stem) $1\frac{1}{2}$ -3 inch. basi incrassati, foliaque præsertim subtus ad venas ferrugineo-pubescentia.

Lamina coriaceo-profunde coidata, apice emarginata integriuscula, subundulata, supra tactu asperula, venis basin palmatis, 7; 2 intermediis branched on the outer side, these branches as well as the primary ones, inosculate by arches interwoven, with reticulate veins prominent below.

Some irregular white spots above, scattered strigose hairs above, pubescence underneath stellate.

Peduncles in the specimen 3, (appearing to originate from a protuberance on which are the scales,) axillary base surrounded with brown linear subulate scales or bractes, very strigose hairs subpungent subferruginous, otherwise greenish.

Capituli of flowers, oblong or nearly spherical, greenish from the perianth, otherwise brown from prominent Pistilla. There do not appear to be any bractes.

Perianths both tetramerous, the outer of 4 spathulate slightly concave scales, densely covered with white straight hairs outside. Inner 4-partite, herbaceo-fleshy segments, patent-reflexed at the apex, hairs like the outer ones on the back except at the base inside which is smooth, perhaps valvate in æstivation.

No rudiments of stamina.

Ovary strigose.

Style scarcely any, or style 3-partite, segments revolute reflexed outside hairy and inside stigmatic channelled.

Stigmata 3, 1-ceteris majus, uniloculare. Ovula 2, (1 abortiens) anatropa pendula no distinction of teguments, solid, no embryo sac, I could make nothing out of the barren ovule. The ovula in the young fecundated state, I take to be campylotropous; although I cannot reconcile this with the subsequent appearance of the seed. In the specimen the ovaria are generally fecundated and hence enlarged, in the abortive ones, the pistilla is of the length of the inner perianth, which is partite below the middle, and easily separates into its constituent portions.

The stigmata are often two in which case they are nearly equal, except the hairs, all the parts of these are black.

Fructus (immaturus) in the specimen solitarius, (capitulis aliis abortivis) pendula maximus, capitis humanis magnitudine (very heavy) e carpellis plurimis, apice angulatis more Nipæ vel Pandani quodammodo conflatus.

Fruc. proprii ambitu cuneato-obovati, in the exposed parts greyish-green, in the appressed pinkish, very strigose with deflexed sticking, but scarcely pungent hairs, deeply furrowed sides, apex angular analogous to Nipa. When very immature, cellular fleshy with many fibres, along these on a long section mucilaginous matter is thrown out, this is the prevalent secretion of the plant. The walls of the single cell smooth, with small spot-like eminences here and there; from the immature specimens, it may probably be drupaceous, indeed the apex is already hardened.

Seed, one, pendulous, compressed, raphe $\frac{1}{2}$ complete, linear simple. Tegument single lax spongy cellular, the young albumen copious.

Radicle broad flattened furrowed, superior, longit. (quoad fruit) shorter than tegument, which towards apex is entirely spongy cellular, adhering here to the albumen.

Cotyledons very small, suborbicular, on the same plane with the raphe, which appears simple $\frac{2}{3}$ complete.

HAB. It was brought in from B. Brouang, nom. Malayan vere *Akur Pisang Pisang*, the seeds (or fruit) are eaten by natives.

Obs. It is easily distinguished from the Ayer Punuus species, by the shape of the leaves, and the immense fruit and differs from Wallich's *P. gigantea* which has the outer perianth united at least in the male.

That may be called *Callicarpa*, this *Macrocarpa*.

Its affinities are obviously near those of Menispermeæ, it is perhaps analogous to some Urticeæ, out of flower no one would know it from the former family. (N. B. Examine the Assam climber which I take to be *Natsiatum*.)

It is abundantly distinct however in the capitulate flowers, in the binary double perianth, and concrete compound pistilla, each with 2 ovula as well as in the structure of the wood, and especially that of the pith.

In the edible seed? it assimilates to *Artocarpus*, and in the inner perianth to some Urticeæ, particularly if the stamina be opposite the segments.

In the branches on which leaves are frequent, and the petioles are not inserted into foveoli, which I take to be annual, the pith is large, consisting of firm closely packed roundish cells, containing a few adherent granules, its cells become smaller outwardly. Transverse section of the pith, consists of truncated cylinders short, applied end to end.

It is surrounded by true ligneous tissue, with large tubular openings here and there, and distinctly striate, its outline is irregularly angular.

Between this and the bark is occupied chiefly by cellular tissue, angular muriform towards the wood, hence roundish, but towards the bark it is irregular.

In this in the sinuses of the angles of the *wood* appears the parallelogrammic plates, and between these and the bark, but *all round*, is a formation of young fibrous tissue, the commencement of the next true wood.

Parallel plates of membranous impunctate tubes! each surrounded by highly punctuated fibres of considerable diameter occurs; of the extent of these membranes I know nothing, and sometimes they are partly punctuate. Their presence is confirmed by the transverse section of the other species made by my friend Mr. J. W. Grant, C. S. sometimes the membranous tubes have here and there no interposed fibres.

In the main, or larger branches, there is a distinct ring round the pith, the truncated cylinders of which are now beautifully punctuated. This ring is not visible on a thin transverse section, it is continuous with the wood, than which it is less tubular, but has no line of demarcation.

Then comes the former wood with 8 radiating lobes, owing to the parallelogrammic plates, which appear now nearly to reach the pith, but the new formed part, is, I think, or will be wood, from its presenting largish perforations. The new formed outer part of each plate has a whitish cellular appearance very different from that of the old.

The white cellular tissue,—the ground work of the structure, presents between the first wood and the bark (outwardly less complete,) 3 new ligneous formations. The first is well enough developed, generally no new distinct parallel plates are to be seen, only in one case in which it was opposite to the main one.

On the circumference of each woody tubular system, occurs mucilaginous tissue which appears to consist of developing fibres generally in that round the 2nd wood, divided into wedge-shaped lines, the wedges having their narrow

end, outwards; many of these under 1-inch C. M. look like parallelog. tissue, but I think they will be fibro-vascular.

It is singular that the outer limit should be marked with an opaque punctum, which looks detached, the fibrous tissue not having reached it. The outline of the 2 wood is irregularly lobed. Compare these observations minutely with such as have reference to previous species.

Pl. CCCCLXXXVII.

1. Plant reduced nearly $\frac{1}{2}$.
2. Female inflorescence.
3. Female flower, these small ones were all abortive, but probably represent the flower as per anthesin.
4. Same, perianth outer removed, hairs should be carried to the top.
- 5, 5. Pistillum of the same.
6. Long section do.
7. Flower after fecundation magnified about 7 times.
8. The same outer perianth spread out.
9. Same inner do. laid open.
10. Long section of pistillum disclosing one growing and one abortive ovule.
11. The two ovula detached.
12. Growing ovula do.
13. Long section of same or as seen under graduated pressure.

Pl. CCCCLXXXVIII.

1. Fruit immature ($\frac{1}{2}$ nat. size.)
2. One of the carpella detached nat. size.
3. Long section, young seed removed, at *a* endocarp hardened, at *b* barren ovula.
4. Long section, seed in situ, *a* hardened part of endocarp, *b* barren ovula, *c* funicle, *d* micropyle, on the front face is represented the raphe.

5. Long section of young seed, *a* spongy flesh solid apex of teguments white towards the albumen.
6. Young album, *c* embryo.
- 6*b*. Embryo.

3. *Phytocrene calicarpa* Gr. *feminea planta*, Pl. CCCCXC.

Fructus e carpidiis multis in capitato globoso sessili dispositi obovati, infra medium nudiusculi pressione angulati, supra setis subulise his retrofactis hirta densissimis tecta.

Ima basin sepalis 4, e basi lata triangular setaceo-acuminat.

Perigoneoque membranaceo, sepalor. in modo pubescent. ad medium 4-partit. lacinis latis subcordatis.

Apex imus nudiusculum centro stylo brevis robusto exserto.

Ovar. (less developed, of the same shape, the apex nudiusculous however is longer, 3-4 gonol ending in a short thick black hirt style and 4 linear ovate recurved stigmata, these are opposed to the divisions, of the perigon.) 1-loculare, ovulis 2, 1 abortive anatropus ex apicem loculi pendulis, an nuclearibus an teguments uno prædit. lacinis mucilaginif. in apicem Pistilli.

Fructus 1-locularis, Endocarpio areolato-rugosa sub lente cellulosa. Mesæcarpio subosseo fibros (immatur.) vix separabilis, superfcie rugosa, apex solidus lacunis mucilag. sursum ampliorib. exceptis.

Semen pendulum cavitat. implens, superfcie irregulare hinc raphe conspicuscula fere $\frac{1}{2}$ complete.

Tegument. cellulosa farinacea integrum vix separabit. basin fibrosam.

Albumen carnosum copiosum, forma seminis transversely sigmoideo-carvatam, extus superfc. rugulos. papillos. intus læve nitensque.

Embryo cotyled. maximis foliaceis accumbent. sigmoideo-flexis transverse. Radicula brevissime supera hilum prope. Plumula inconspicua.

I have only seen the abortive ovula which are withered and compressed. I think there are appearances of one tegument

and a nucleus. In the fecundated ones figured, the main bulk is loosely cellular, with a tendency to breaking up in the centre. The upper half is occupied by a cellular body, which is attached inferiorly, this near the situation of the foramen, contains the embryo, the lower half is entirely cellular the upper scarcely so, I can see no defined edge to it, or other appearances to lead me to think it is a nucleus containing an embryo sac.

In the disposition of the cotyledons this approaches an Assam Menispermæa.

It may not perhaps be of the same genus as the *Phytocrene* figured in Wall's male flower; for, in that there is a one-leaved involucre, and there appears some difference in the construction of the wood.

The longitudinal undulations of the whole seed, or its transverse sigmoid flexure is not a little remarkable, inasmuch as it exists totally independent of any inflexion of the putamen or testa.

The 4 stigmata are against its being *Urticeæ* and so is the general structure which approaches more to *Menispermææ*.

1. Fruit-bearing stem. nat. size.
1. Fecundated pistillum, surrounded at the base by the perianth, and in this case 4 alternating bractes.
2. Long section of the same, the ovulum at first sight appears antitropous.
3. Same fecundated ovulum removed, on the posticous face of its cicatrix is a black minute body, the abortive ovulum.
4. The abortive ovulum, appearances of, raphe as well as of foramen.
5. Fecundated ovulum, *a* raphe, *b* micropyle or at any rate situation of radicle.
6. Same, long section, *a* embryo-sac, containing the young embryo in its apex.

7. Embryo sac detached, its lower $\frac{1}{2}$ is cellular, this is the young albumen.
8. Embryo.
9. Immature fruit, perianth, and in this case several bractes.
10. Long section, complicated appearances, a lacunæ containing mucilage, *b* pyrena, the reniform spots are due to the section running variously through its irregular surface, *c* tegmen of seed, *d* albumen, *e* cotyledon in centre, *f f* do. at the margins, *g* radicle.
- 10a. Armature of fruit.
- 11, 11. Seed detached the raphe and indentation of surface shewn.
12. Transverse section of albumen, and cotyledons both sigmoidly flexed.
14. Do. of albumen cotyledons removed.
15. Embryo separated, rather oblique view.
16. Same.

4. *Phytocrena gigantea*, Pl. CCCCXC. Fig. II.

1. Perianth.
2. Involucra or calyx laid open.
3. Corrolla removed with the stamens.
4. Do. laid open.
- 5, 6, 7. Stamina.
8. Pollen.
9. Rudimentary ovarium.
10. Long section of do.
11. One of the hairs.
12. Transverse view of the branch cut transversely.
13. Do. section of wood.
14. Do. of the medullary rays.
15. Vessel surrounded by prosenchyma.
16. Joint detached.
17. Prosenchyma.

NATSIATUM.

1. *Natsiatum*, Pl. CCCCXCVI. Fig. I.

Frutex dioicus volubilis, scandens, racemis pendulis pubescentibus, pedicellis arcuatis sursum? bracteatis, bracteis linearibus pedicellis paullo brevioribus, floribus parvis inconspicuis lutescente viridibus, pubescentibus ut etiam pedicellis.

Sepala 5 lanceolata acuta basibus connata.

Cor. urceolata 5-partita laciniis lanceolatis acutis conniventibus sepalis alternis.

Torus dilatatus. Glandulæ 5 carnosæ crescenti-formes, apicibus incrassatis capitatis petalis opposita, an e 10 periparia connat. staminibus externe sitæ.

Stam. 5 sepalis opposita, inclusa, filam. brevissima crassiuscula. Antheræ adnatæ sagittatæ oblongæ biloculares, longitudinaliter lateraliterque dehiscentes. Connectivum medium versus dorso glandulosum. Pollen?

Rud. fæmino centrale, e pilorum massa erectorum pilis illis perianth. similibus. Æstivatio valvata.

HAB. Assam Legi Solani Mookh: Jan. 1836.

STAUNTONIA.

1. *Stauntonia trifoliata* Gr. Pl. CCCCXCV. Figs. II and III.

Frutex volubilis longe scandens, glaber. Rami novelli leviter striati.

Petioli longe, utrinque incrassati et articulati, teretiusculi supra planiusculi sæpe spithamæi.

Petioluli, inæquales laterales breviores centrali unciali, subcanaliculati. Folia 3-foliolata. Foliola inæqualia terminali majore, ovata vel ovalia, obtusa cum mucronem vel

retusa, integerrima, chartacea, supra suturati-viridia, infra glauca, basi 3 venia, marginibus subrevolutis.

V. secundariae paucæ irregulariter nexæ, accessoriæ plures, pagina cæterum venulis reticulata. Stomata paginæ inferioris.

Flores monoici racemosi, racemis vel simplicibus aggregatis, vel basin divisio ideoque paniculatis petiolis brevioribus basi bracteis scariosis brunneis, suffulti.

Pedicelli mediocres apicem in annulum dilatati, (interdum medio, interdum subflorem bracteolata,) basi bractea lanceolata brevi suffult. in racemo articulado.

Flores nutantes utrinque sexus similes lutescentes nutantes, fæminei racemi basin versus siti, pauciores, omnes in pedicelli apicem articulati; alabastra glaucescentia ovata.

Sepala tria ovato-oblonga carnosæ submarcescentia, intus processibus irregularibus carnosæ cellulosæ obsita, æstivatione valvata patentia.

Processus petalorum 5-seriatim, intermediis minoribus, uti cristæ describendi, sepalorum maris obsoleti, fæminæ obsoleti, petalorum fæminæ sine ordine disposito.

Pet. patentia angustiora æstivat. distantia subcarinataque processibus supra descriptis, totam paginam internam occupantibus an pauciores in florib. masculis.

Glandulæ 6, lanceolatae carnosæ albæ acutæ, vasc. fasc. tenuissimo media versus evanido, filamentis basibus adjecta, biseriata, seriei ex sep. inter: petal. opposit.

Stam. 6 biseriata, seriebus ut e glandulæ alternant. Filam. leviter connata, intus convexa, extus plana, breviuscula, alba.

Antheræ biloculares extrorsæ, oculis discretis linearibus longit. dehiscent. connectivum maximum carnosum ovatum apiculatum rugosulum, ultra oculos longe product.

Pollen ovatum, 3-sulcat. glabum. Pistilla abortiva tria cava, vacua.

FÆM. tegument. maris, glandulæ totidem minores.

Stam. abortientia, formæ perfectur. sed multo minora.

Pistilla tria sepalis opposita glauca glabra angusta et irregulariter ovata, 1-locularia sutura ventralis interna. Placentæ totam faciem internam pistilli cæjusque occupantes undique ovuliferi. Ovula minutissima globosa, simplice, tegumentis nullis. Interior locule cæterum nuncupata, filis cellulosi septatis hyalinis, e parte locula parietes interne suturæ ventrali exacte oppositi orientes.

Styli nulli stigmata ovato-conica viscosissima aspectu lucido

Fructus sessiles tres bini vel solitarii oblongi obtusissimi. (like a short sausage) digitales, sutura ventral. latâ sed parum profunda, extus argenteo-cinerei creberrime ferrugineo lepidoti, parietibus coriaceis 1-loculares, loculo pulpa alba omnino repleto centro quasi fistuloso.

Semina 00 in pulpum nidulantum et peripheriam versus sita, hilo minuto centrifugo, ambitu cordat. sinu extrorso, majuscula, immatura tantum visa.

Testa lævis lucida, extus aspectu striato, intus viridis carnosâ.

Tegument interius liberum nullum. Albumen copiosum hinc ad hilum latus excavatione minuta.

Structura ovarii, singularis, et forsân Butomeis Flacourtiensisque.

Character specificus ad Stauntoniæ e Tingrei referens.

Foliis 3-foliatis, petalis intus 5-cristatis, filamentis connatis. Tingrei.

Fol. 7-tenatis, petalis intus lævibus filament distinctis.

Male flower. Fig. II.

1. Male flower bud.
2. Do. sepals removed.
3. Male flower open.
4. Do. sepals removed.
5. Gland viewed as a transparent object, an incomplete vascular fascicle is seen.
6. Stamens and glands.

7. Do. (one too many!) laid open, to shew the slight cohesion of the filaments, and the 3 abortive ovaria, pistilla.
8. Pollen viewed dry.
9. Do. immersed.
10. Abortive pistill. inner or ventral face.
11. Do. laid open along the ventral inflexion.

Female flower. Fig. III.

1. Female flower.
2. Do. sepals removed. 2. Petal shewing the cellular processes.
3. Pistilla glands and abortive stamina.
4. Transverse section of ovarium.
5. Long section of a pistillum.
6. Transverse of do. shewing that the placenta occupies the whole face of the cell, that part immediately corresponding to the ventral suture producing abundance of cellular filiform articulated processes.
7. Two ovula, from the open flower.

The same.

Frutex scandens, foliis 3-foliatis, lanceolatis acuminatis terminali longius petiolutato, articulatis! Petiolo communi basi tumido. Racemis aggregatis, ramulos brevissimos, squamis scariosis tectis, terminantibus. Pedicellis filiformibus basi bracteatis, rubescentibus floribus lutescent.

Sepala 3, lanceolata acuminato-conniventia (æstivatione valvata) venosa.

Pet. 3 his alternantia duplo angustiora pauloque breviora, sepalisque intus rugosula glandulæ hypogynæ 6, oblongæ carnosæ integræ, 3 vix exteriora sepalis, 3 interiora pétalis opposita.

Stam. 6 filamentis basi in columna leviter coalitis brevissimis. Anth. adnatæ, biloculares extrorsæ, 1 interdum

abortiens. Connectivum ultra antheram in processum linguiforme, subulatum product, loculis linearibus.

Pollen lanceolata, læve medio sulcatum.

Rudim. ovarii centrali, terete subulatum 3-sulcatum, processibus subulatis 3 format.

Fructus compositus e carpellis 3, an pluribus sæpe aborta solitariis ovatis ovi magnitudine, baccatis, hinc utrinque sulcatis, sed parum profunde, 1-locularis cavitata. magna pulpa copiosa in qua semina nidulant. centraliter densiore gustu dulci et suaviuscula repleto. Semina horizontaliter sita, compressa angulata, atra hilo lineari excentrica quoad axin carpelli, parietibus nempe contiguo brunneo notat.

Testa membranaceo-coriacea nitida atra, albumen carnosocorneum amplum. Embryo minutus in cavitata albuminus situs et hilum prope loculos, orthotropus. Radicula crassa obtusa hilum versus spectans. Cotyledones plana convexiusculæ ovatæ incumbentes quoad situm transversate seminum et diametrum transversam majorem. Plumula non examinum.

HAB. Khasyah Mountains. In sylvis Churra: Oct. 16th, 1835, and Nungklow: Nov. 15th, 1835.

2. *Stauntonia filamentosa* Gr. Pl. CCCCXCV. Fig. I.

Frutex scandens, cortice cinerea suberosa. Rami virides læves.

Folia alternantia. longe petiolata (petiolis teretibus obsolete striatis utrinque incrassatis spithamæis,) septenatim digitata, obovato-oblonga acuminata fere caudata, integra glabra subcoriacea, supra saturati viridia, subtus albidoglaucæ. Venæ secundaria medium $\frac{1}{3}$ supra arcuatim nexæ arcubus venulas etiam arcuatim nexas emittentibus interstitiis omnibus reticulatis, margines subincurvi, folia axin proxima ut etiam petiolule minora, illa flores fulciantia aliquoties minora, inferiora 6-nata, intermedia 5-na, summa 4-na.

Racemi axillares paniculati in axi communi brevissimi bracteatae inserta, basi bracteatae, bractea ovata, viridi concaviuscula, rubri carneive. Bracteolae florem quemque fulcientes albidæ angustæ pedicellos brevis æquantes apicibus reflexis, alabastra, quæ tantum vidi, ovato-oblonga, ascendentia, fusco-viridia.

Sepala æstivatione valvata ovato-oblonga obtusiuscula carnosæ, apicibus crassis subinflexis saltem faciei interiori. Petala his alternantia lanceolato-linearia, sepalis $2\frac{1}{2}$ angustiora, paullo breviora, luteo-viridia, apicibus crassis. Gland 6 hypogynæ, late obovatæ, staminibus oppositæ, cum his separant. basibus filament. nempe adnatis, viridibus apice lutescent.

Stamina 6 hypogyna, 3 exteriora sepalis opposita, 3 interiora petalis opposita.

Filamenta ima basin leviter coalita, brevia sub 3-gona, angulo 3-tio interiore crassa. Connectivum crassum carnosum apice subulato ultra antheras breviter producto. Anth. adnatæ extrorsæ vel anticæ biloculares longitudinaliter dehiscentes, loculi angusti lineares.

Pollen album, læve ovato-lanceolat. hinc sulcat. Rudimenta fæmineorum 3 centralia teretia, apicibus obtuse conica, ibidemque lucida secus faciem internam sulcatæ, vero convoluta sunt.

HAB. Assam. In sylvam cum Theâ consociata occurrit
Tingrei: *Feb.* 23rd, 1836.

The rudiments are convolute, they have one vascular fascicle (spiral vessels and ducts,) which towards their apices are much increased in number.

The third sepal is posticous or next the axis.

The glands are probably representatives of petals, the inner series of which are therefore transformed, the alternation of parts is throughout natural.

BETA.

Betæ sp. Pl. DXXV. Itinerary Notes, p. 216, no. 85.

Affinitas certe cum Urticeis, for it agrees in habit, in separation of the sexes, in the male perianth, in the anthers and their relation to the leaves of the perianth, in the aggregation and subcohesion of the female flowers: in the structure of their perianth and its relation to the ovary, in the structure of this, as well as in the structure of and non-correspondence in the number of stigmata, and in the ovulum.

The want of vascularity of the ovarium, and consequently of the stigmata is very remarkable. The want of bracteæ to the flowers of female sex, is also worthy of notice. Although the stamina have no vessels, and although the female flowers may be axillary, still the male floweres are most developed; a fact worthy of much notice.

The male inflorescence is inverse; the female is simply axillary.

The curious cells of the superficies must not be passed over.

If Beta had stipules why should it not be Urticeous?

ASIPHONIA.

Asiphonia piperiformis, Gr. Pl. DXXVIII. Fig. I.

Frutex subscandens. Caule ramisque articulatis ad articulos incrassatis. Fol. alterna vel distincti subpatentia vel subpendula, breve petiolata, e basi ovato vel subcordato ovato-acuminatissime caudata integra subtus pubescentia, basi 5-venia, venis 2 lateralibus evanidis cum lateral. exterior intermedia primar. cito confluentibus, hæ intermedium apicem versus cum 2 secundariis costæ arcuat. interveniis cæterum transverse venulosis interstitiis reticulatis.

Inflorescente cymoso corymbosa terminalis et axillam folii penultim.

Fl. sursum subsecundi erecti, inconspicui inertio viridescentes demum purpurascens. bracteis linearibus setaceo 2 lateralibus centro 0!

Ovar. breviter pedicellat, rotundat. 4 gonum dense pubescens.

Per. carnosum rotatum, sepalis 3, cordatis extus pubescent intus reticulatis, in alabast. depresso ambitu obsolete 3-gono.

Stam. 1-seriata, 8-10. Filam. 0. Antheræ connectivo carnosæ glandulosæ pubesc., extus curvata marginibus curvatis adnatis, biloc. locul. distant. longit. dehiscent. Pollen granulosum, grannula in aqua deciduis.

Stigma centrum genital. disci implens lobato-sinuosum.

Stylus 0. Ov. 4-loculare, loculis minutis angulis respondent. Placentæ cruciatum centro cohærent. Ovula in cuique loculo 00, biseriata serie una e quaque marginam inflexam, anatropa minuta.

Fructus siliquiformis, immatur tantum visi.

Caulis 4-sulcato canalicul. e medulla centrale rotundato magnum corticeque tenui. Lign. exconcentric. radiis medullariis conspicuis, densiusculi vasis majusculis sine ordine sparsis, composit. e fibris tenuibus vasisque *cellularly* punctuatis.

Ligin. Menisper. Piperac.

Odor. Piperaceus, caulisque foliaque.

Perianth Anonacearum.

Fibres not unfrequently punctuate, bases with coniferous markings, often obscured by the enlargement of the central disc as in most woods.

HAB. Malacca ad marginum viæ sylvaticæ inter Ayer Punnus, et — $\frac{1}{2}$ way.

SP. CHAR. Per. rotatum, 3-sepalum, (tubo nullo) stam. uniseriata.

Ovar. 4-loculare, stylus 0. Stigma discoidea sinuoso-lobat.

Fructus siliquiformis.

Frutex scandens facie Piperis.

Rachibus inflorescent. subincrassatis.

The bractes can scarcely be considered as belonging to the flowers, as the insertion is always a little above, and

often a good way, this however may depend upon partial elongation of the rachis.

Under each branch of inflorescence is a conform. but larger bract.

Asiphonia Pl. DXXVIII. Fig. II.

Fructus siliquosus, subtorulosus stipitatus, 4-valvis.

Replis non interjectis.

Placenta libera centrali, 4 gona, valvis dorso striato-costat. seeds in single series along the flat faces of the placenta, which are opposite the valves, sub 3-angular placed end to end in a moniliform manner externally rugose greyish.

I have only seen abortive ones.

The characters of the fruit approach closely to those of *Ascoma*, perhaps the only difference is the want of the alternating reploid lines.

THOTTEA.

Thottea grandiflora Pls. DXXX. and DXXXI.

Frutex 3 pedalis, robustiusculus, apice parce ramosus.

Ramulis pubescentibus. Folia alterne exstipulata sub disticha subsecunda oblonga vel obovato-oblonga superiora (ramulor.) majora coriacea cuspidata brevi lataque, breve petiolata subtus dense pubescente hirta venulis ultimis etiam subtus elevatis.

Racemis ex axillis folior. lapsor. caul. pubescenti hirtis, 2-3 unciali nutantibus, bracteis distichis lineari-oblongis subcarinatis.

Flores amplissime penduli longitudine fere 5-unciale latitudine extreme 4-4½ unciale, colori luridi purpurei, interveniis irregulariter albo-maculata (dashed.)

Perianth. campanulat. membranem petaloid. æstivat. valvat. apicibus subinflexis, venis primariis conspicuosis tactu scabris, basilaribus intermediis incompletis varie nexis, margine re-

volutis intus filamentis floccis confervoid vel fungiform, lilacinis dense vestitum.

Fundum corollæ nidificatur, columna brevis purpureo-sanguinea.

The perianth is fleshy at the base and throughout, tears readily, its inner surface is irregularly undulated and has altogether a mealy appearance.

Stam. biseriata seriebus suboppositis, filam. brevia carnosa.

Antheræ adnatæ, loculis 2, angustis. Pollen concavo-convexum punctulat. in aqua, subsphæric. superfice granulosa. stigmata 13 radiantia quasi insuper seriem summam stamen superumpositum, radiis convexiusculum, radiis fund. 4, in centro in crucis formam, meeting, 4 alia interjecta as the 4 primary ones diverge, a very curious conformation.

Superficies radii supera aspectu glutinoso.

Stigma fungiform.

Ovarium tortum spirale. oblongum, pube brunneo-hirtum. omnino inferum 4-loculare.

Fructus siliquiformis siliquam Hyperantheræ simulans, 4 uncialis utrinque subattenuatis, breviter pedicellatis subtortis angulis 4, prominulis, rotundatis, asperis, pube brunneis, subtorulosis, valvis *carinatis* 4-valvis, completa, *placentis* liberis factis in form. filament. Placenta libera carnosa, 4-angularis.

Semina pauca oblongo-ovata, in concavitate. placent. lateral. quasi nidulant. et cellulosa, tela ejus vestita, ideoque aspectus cellulosus punctis nudis? brunnescent. paucis exceptis pendulis, angulis affixa, huic convexa hinc convexa trigona.

Tegum. exterius spongioso-cellulosum, superfice irregularia.

Tegum. internum induratum. subosseum brunneum superficiem undulat. intus nitidum.

Albumen copios. carnosum, cavitat. tegm. inter. conforme.

Embryo minimus hilum prope in cavitat. albumen. ovatus dicotyledon, materia gelatinosa circa an sacculis embryonar. reliquis, orthotrop.

Tegum. terti. memb. cellulos. tenuis ultra album apicem in apicul. product.

Ovarium angulis 4 rotundato dense pilosum, loculis totidem sectione transverse 3-angularib. angustis, placentis cruciata crassa, angulis alterna, ramis quoque extus 1-vascular. Ovula pauca minuta pendula oblonga, prope hilum. tegumenta bina, interius abbreviata, ore simpliciora solito, exterius vesiculos. sed verisim. ex *abortionem*.

Aromata, habitu, partu numero ternario, albumine sub-ruminato embryoneque Anonaceis affinis.

Generic diagnosis, consists in the campanulate perianth number and double series of stam. and the stigmatic lobes having no relation to the ovarial cells, et in finis ovario 4-loculare ! upper stamens sub 16, under ditto sub 18.

Caulibus fructigeris ex ascidiis scandentibus glanduloso pubescent, pube parte novell viride ferrugin.

Fol. distant. petiolo breve basi dilatato, lamina elongato-lanceolata, infra in petiol. attenuata producta (ideoque fol. sessilia) coriacea integerri. subtus pubesc. supra 1-venia, subtus costa prominula, venulis 2 endogenosis, margine versus indistinctis, costa apice product. in cirrhus dense pubesc. apicem coniform.

Panicula terminatis ferruginea, sepalis foliaceis reflexo-patentis, fructibus oblongo-clavatis apicem quasi truncatis, rotundatis 3-4 gonis. Pedicellis fl. infra 2-3 floris, sursum 1-floris.

Caulibus ascidigeris terrestribus abbreviatis, foliis confertis, sessilibus $\frac{1}{2}$ amplexicaul. petiol. ascid. ferrug. pubesc. brevissim biuncialis.

Ascid. subovuta ovi gallini magnitud. in terr. recumbent. ore constrictiuscum venulosa, more endog. *dorsali* O.

Cristis 2 *posticis* maximis pulchre fimbriatis, os simplex, margin very deep and nearly perpendicular, utrinque simplex, rugis well developed.

Lamina angustissime spathulata sessilis recumbent. in ascid. ad basin anticum processugerum.

Color. oris viridescens, ampullæ et laminæ, viridescens maculis sanguineis.

HAB. Malacca Paddam Bhattoo, montis Toondook.

Paniculis fl. mascul. racemiform subcylindræis, oppositifoliis (vero terminal) axilla fol. superum gemma parent.

6. *Nepenthes* sp.

Caulibus longissimis scandentibus ramosis, ramis crowded with ascidia, supra foliosa, fol. distant. cortice vetustior suberosa.

Fol. ramor. ascidig. conferte imbricat. sessilia e basin cordata $\frac{1}{2}$ amplexicaul, alter. in cirrhum brevem robustum $1\frac{1}{2}$ unciali.

Ascidia creberrim. erecta subovata compressiuscula venulosa (endogen.) cristis 2 posticis maximis bifimbriatis, lamina spathulata, dimid. longitud. ascid. subavenium supra, subtus bivena obsolete et basin prope processus 3 sessiles gerens.

Os ad insert. laminæ quasi *emarginato* fere horizontal.

Margo profundus obliquis, os constringens.

HAB. Malacca Ayer Punnus.

Allied to the *Puddam Bhatoo* species.

Nepenthes from Botanic Gardens, Pl. DXXXII.

Chiefly worthy of notice on account of the difference of development between the ovula of the upper, and those of the lower portion of the panicle.

Thus 5, 6, 7 represent anatropous ovula with two distinct teguments, from lower part fig. 8, from upper, part antitropous ovula with one coat.

This is very curious, there are some reasons for believing, that the coat of the antitropous ovula is the inner membrane, the outer being abortive, because it resembles considerably the inner coats of the anatropous ovula, and because the long funicle is evascular, while in the others there is a raphe.

The mode of attachment of both requires to be examined, as well as the ovula towards the middle of each inflorescence.

The carpella alternate with the sepals.

1. Female flower.
2. Stigma of do.
3. Ovary transverse section of.

4. Portion of a carpellum and one of its placentæ, from an ovary of the lower part of the panicle.
5. Ovula from do.
6. Ovulum do. testa open longitudinally.
7. Ovulum. Testa and tegmen opened.
8. Ovula from upper part of spike, the process at the foot of the long funicle requires examination, nucleus adherent to tegument.

CASSYATHACEÆ.

CASSYTHA.

Cassytha filiformis,

Herba in fruticibus parasatica aphylla eisque spongiolis concavis ad nexa. Caules volubiles, glabri striati. Flores spicati parvi albi virescentes. Spicæ paucifloræ, basi 3-bracteata.

Perianthium basi squamatum tubo brevi, limbo profunde 3-partito, sepalis ovatis erectis. Bracteolæ 3, nanæ, tubo affixæ, sepalis alternantes. Æstivatio valvata.

Stamina triplico ordine disposita, nempe 3-6-3, exteriora petaloidea, introrsum bracteolis opposita. Intermedia 6, quorum, 3 basi 2-glandulosa extrorsa seriei externa opposita, 3 basi nuda, introrsa, ordini tertio opposita. Filam. horum 6 clavata, brevissima ordo tertius sterilis, e glandulis oblongis formatus. Ovarium 1-loculare, 1-ovulatum, ovulo pendulo, stylus brevis subulatus, stigma obtusum.

Pericarpium calyce ampliato baccato apice pervio tegmentorū exuviis coronata obtectum, 1-spermum. Semen pendulum. Testa membranacea tenuissima. Cotyledones, crassi plano-convexi. Radicula supera, brevis. Plumula conspicua, 2-phylla, foliolis plano-convexis.

Mr. Brown describes the exterior anther as introrse, the interior extrorse. Nees Von Esenbeck, the 3 interior as ex-

trorse, I find them alternately introrse and extrorse, thus the outer petaloid series, is introrse; those with 2 glands at the base are extrorse, the 3 remaining are again introrse.

The outer series of the perianth I call bracteolæ, as they resemble entirely those at the base of the calyx and of the spike.

AQUILARACEÆ.

AQUILARIA.

Aquilaria Agullocha.

Per. campanulat. tubo partit. laciniis ovatis patentib. pilosis æstivatione imbricatis æqualibus.

Stam. monadelphia in tubum calycis conformat. arcteq. applicitum coalita, 10 alterna fertilia, 10 sterilia squamiformia, dense barbat. Filam 10 antherifera, glabra, 10 sterilio pilosissime exserta subæqualia. Anth. erectæ subexsertæ bilocul. longit. lateraliterque dehiscentes.

Stylus brevissimus. Stigma capitat.

Ovarium pilosissim liberum, 1-loculare, dissepimentis 2 parietalibus valde incompletis, 2 ovulat. Ovula parietalia pendula ab apice locul. foramen superum hilum prope.

Arbor. ramis hirsutis, fol. alternis exstipulatis lanceolato-acuminatis integris venis secundariis margines usque currentibus. Paniculis compositis racemoso umbellatis, floribus inconspicuis. Cl. Lindley ait "foramen ad apicem ovuli" an recte? ob ovuli formam potius hilum prope.

Ex siccam speciem Cl. Lindl. donat. Mergue: *Dec.* 1834.

Primo aspectu, stam. vere perigyna, filam. in tubum calycinum decurrent, fauce squamis 10 appendiculata, tuboque calycis piloso, sed stamina et squamæ dissectione calycis parietibus separabilia, nec accreta sed mere applicata sunt tubo calycino.

HERNANDIACEÆ.

HERNANDIA.

Hernandia ovigera.

Ramuli robusti, fol. alternis exstipulatis supra lucidis. Paniculis corymbosis, paullo supra axillares.

Habitus foliationis Euphorbiaceus, vernatio conduplicata.

Pedunculis partialibus umbellatis. 3-4 floris. Bracteis 3-4, involucelli modo nunc disposit. nunc uno dislocat.

Fl. monoica suave oleatis.

Masc. tuba subnulla sepalis 3 ovatis sub coriaceis imbricatis æstivat. patentibus. Pet. 3 alternant erectiuscula.

Stam. 3 antherar. valvis revolutis, sepalis appositis, filamentis brevibus utrinque staminodio auctis, corpusculis interioribus interjectis.

Pollen Aurantiacea.

Fem. Calycis tubus ovulis, calyculo semi-inclusus. Sepalis petalis 4. Stam. 4. staminodia sæpius obsoletis.

Stigma magnum reniforme fungoid, stigmatic canal open.

Ovar. 1-loculare inferum ovulum 1, pendulum, raphe enormously prolonged beyond the base of the nucleus.

I see no mention made of the valvate dehiscence of the anthers! Lindley places it near *Thymaleæ* although every thing points out its affinity to *Laurinæ* and especially to *Illigeraceæ* from which perhaps it is scarcely different but I have not seen the seed.

The calyculus of the females is well worth bearing in mind, with reference to *Santalacea* and *Loranthacea*.

In these valvular anthers the loculi are only two, and instead of dehiscing along the centre, the whole of the anther separates anteriorly along the connectivo.

The anther of *Hernandia* represents exactly a leaf with a thick midrib, the lamina inflected to the midrib. To reduce the ordinary 4 locular antero-posterior type, they ought to have a septum in the centre, and each part a line of dehiscence along the centre. See Pl. DXXXV. Fig. II.

Are they due to confluence of the anthers or are the anterior cells alone developed. How are they to be reduced to a type in which the dehiscence takes place along margin of the leaf.

THYMELACEÆ.

CANSIERA.

Cansiera zzyphifolia, Gr. Pl. DXXXVII. Fig. I.

Frutex scandens, fol. alternis coriaceis carnosis concavis ovato-acuminatis subintegris basi triveniis, cæterum venis secundariis paucis distinctis, æstivat. conduplicat.

Spicis axillaribus, foliis multo brevior media supra florigeris velutinis uti partes novellæ.

Flores bractea parva inconspicua suffult, ivirides, inconspicui.

Perianth. urceolatum, extus papulosum, tubo nempe e basi globoso-constricta, limbo 4-fido laciniis late ovatis $\frac{1}{2}$ patentibus, æstivat. valvato-angularis.

Stam. 4, petalis opposita his medium fere usque adnat. inclusa. Anth. biloc. oblong. introrsæ.

Tegument. unicum? foramen superum hilum prope, stylus subclavatus gracilis deciduus, stigma oblongum papillosum capsula, tubo calycis immulat. scarioso, albo facto, recondit. viridescens, cellulosus indehiscens. Semen pendulum, capsulæ conforme.

Tegument exterius osseum atratum. Interius album membranaceo-cellulosum. Embryo ex albuminosus, præcedentis, radícula supera.

1. Portion of a large specimen nat. size.

- 1a. Portion of inflorescence.
2. Alabastrum.
3. Flower, lobes not sufficiently expanded.
4. Ditto laid open.
5. Partium situs et alternat.
6. Stamina front and back view.
- 6a. Ditto after dehiscence.
7. Pollen immersed.
8. Pistillum long section.
9. Ovula viewed under pressure.
10. Flower.
11. Ditto long section, *a* capsula, *b* seed outer tegument, *c* inner ditto, *d* embryo (longit central line wrong.)
12. Ditto transverse, *a b c d* as above.
13. Embryo.

HAB. Common all over Affghanisthan, generally in old or newly cultivated spots or in barren ground, it varies extremely in stature.

SP. CHAR. Racemis pluribus erectis, foliis dense pubescent, floribus spicato-racemosis, tubo medio constricto *dimidiato*. Stigmata oblongo calyce fructus, dimidio supero lapso infero 8-costato.

A genus which it appears to me is intermediate between Thymelææ and Santalacææ approaching much more nearly the former than the latter, with which it assimilates in the tendency to valvular æstivation and pendulous ovula.

To the former in tenacity of bark, habit, stamina, and free ovary.

Cabul: August 10th-12th, 1839.

LEPTONIUM.

Leptonium oblongifolium, Pl. DXXXVI.

1. Portion of young inflorescence.
2. Ditto at expansion of central flower bracte cadiceous.

3. Bud laterally.
4. Ditto nearly vertically.
5. Flower.
6. Ditto perianth laid open.
7. Front } of Anther.
8. Back }
9. Anther burst in front.
10. Pollen.
11. Pistillum.
12. Placenta and Ovulum.
13. Fruit.
14. Ditto long section.
15. Ditto ditto albumen.
16. Embryo.
17. Ditto cotyledons partly separated.
18. Ditto completely.

Drupa oliviformis (4-plo minor) sessilis apice nuda, basi depresso subannulato putamen fibroso-osseum.

Semen 1 basi affixum inter hoc et putamen parietem interiorem tegumen tenui lacerat. membranacie cellulosa, apice putamin. adhærens, et etiam albumini, apice hujus conica excepto.

Albumen copiosum carnosum apice conico nudo. Embryo inversus axilis. Radicul. nudo obovato, oblonga mediocris supra.

Cotyledones 3, *lineares*, intus carinati apices versus cohærentes connatæ? Plumula inconspicua.

This represents pistillum and ovulum of *Champereya*.

H. B. C. *May*, 1843.

DAPHNE.

1. *Daphne* sp. Pl. DXXXVIII.

Frutex 4 pedalis, cortice griseo, fol. articulata. leviter repanda supra saltem seniores saturati-viridia, infra glaucescento-albida reticulataque, flores capitati albi pubescentes, limbo carneo, anth. flavæ, odor mellitus.

Journey from Assam to Ava. Specimen unicum tantum legi. Patkye *Yoommam*, alt. ped. 4500.

2. *Daphne cannabina*.

Frutex, erectus, 6-7 pedalis, fol. alternis exstipulatis, lanceolatis utrinque acuminatis repandis, floribus, capitatis albis, subodoratis capitulis terminalibus.

Per. hypocraterif. tubo $\frac{3}{4}$ uncialis, 4-partitum.

Stam. 8 inclusa biserialia, 4 inferiora majora medium tubi versus inserta, utriusque seriem alternatim, perianth. laciniis opposit.

Stylus brevis. Stigma magna capitula. Ovar. basi annulo glanduloso cinctum oblongum, 1-loculare, 1-ovulata (abort.) ovulo pendulo foramen hilum prope.

HAB. Churra Ponjee: Oct. 11th, 1835.

Daphne cannabina, Lour vix *D. Indica*, ex Donio.

JENKINSIA.

Jenkinsia assamica Gr. Pl. DXXXVII. Fig II.

Frutex scandens, volubilis in cortice paleis brevibus subulatis asperata.

Fol. alterna in petiolis basi paululo supra articulatis ibidemque incrassatis teretiusculis oblongo-obovata sæpius oblique acuminata cum mucrona obtusiuscula subintegra, venis secundariis arcuatis mutuo sed irregularibus nexis, interstitiis venis irregularibus sub transversio-divisis, interstitiis reticulati-

venulosis, stomata paginæ inferioris tantum ad sunt, cuticu læ cellulæ sinuosæ, superioris irregularis vix sinuosæ.

Ramuli ut etiam floriferi sæpius paulo supra axillares.

Fructus capitata, pedunculo furfuraceo subunciali suffulte erecto, 2-5 aggregato distincte baccato, oblongo ovato compresso, stipite crasso insidentis, apice stigmata persistente capitato medio foveolato coronato.

Stipite cincto calyce campanulaceo, 4-partito, laciniis patento-reflexis, argenteo-furfuraceo.

Calyx circumcinctus basi bracteis 4, cordatis, laciniis alternantibus, mutuo unitis in cupulam brevem. Baccæ miniatæ coccineæ, longitudine $\frac{3}{4}$ uncie latitudine $\frac{1}{2}$ unciali.

Semen unicum, magnum, pendulum ex apice baccæ cavitates, subovatum, compressum, secus lateram profunde sulcata, fauce utroque prominentibus 3 paullo elevatis flexuosis, inter se areolatim nexis notatum griseo-brunneum. Areolæ magnæ rugosulæ. Pulpa baccæ parieti seminis adhæret.

Testa coriacea sublignea crassiuscula superfice externa brunnea, cæterum alba, intus glaber, punctulis convexis areolis responbentibus intus undulata.

Tegument proprius tenuissimum, membranaceo-cellulosum albumen arcte vestens, albumen copiosum carnosum cavitati seminis conformes, extus angulatus, subareolatusque, conforming to the testa something, utrinque secus sulcam testis linea rubra notat.

Cotyledones carnosæ oleosæ? planæ axiles, albumini leviter adhærentes, an etiam inter se medio curvatæ marginibus repandis.

Radicula supera in hæmisphærica, albumin exserta. Plumula inconspicua.

HAB. Assam Prope Suddyah: Feb. 3rd, 1836.

De cotyledoni forma et earum mutua adhesionem haud certior. factus sum, unicum fructum tantum examinavi, et quoad cotyledones infelicitèr.

In descriptionem supra, semen pro putamen habenda, con-

tinens semen pendulum unicum, cum tegument simplex tenuissimum, hinc raphe lineari-simpliceo notat.

Chalaza macula indistincta brunnea apicem geometricam seminis prope in Iconenemis dictincta. Chalaza e textura mucilaginoso-fibrosa.

Cotyledones e marginibus et radícula albumina tenuissimo tectis, albumen in super radícula in membranam fere redactum.

Genus novum Thymelexaria.

Flores capitati. Perianth. campanulat. 4-partit. basi involucra 4-fido suffult.

Drupæ stipitatae, pyrena anguloso-areolata in albumen copiosum.

Frutex scandens, hinc illinc cortice subfurfuraceus tenacea foliis alternis, oblongo-obovatis, in petiolis articulatis. Bacis miniato-coccineis.

LINOSTOMA.

Linostoma decandra.

Fruticosa, ramulis compressis, fol. lanceolat. oppositis, acuminatis integris, floralibus discoloribus sessilibus basi subcordatis racemis paucifloris axilla terminalibusque, floribus majusculis.

Cal. tubo cylindrica elongat. profunde 5-partit. laciniis lineari-lanceolat. reflexis æstivatione imbricatis, 2 exterioribus.

Squamæ carnosæ clavatæ sepalorum numero duplo, fauci inserta, alterne sepalis opposita.

Stam. totidem fauci inserta alterna breviora sepalis opposita. Filam. longiuscula filiformia. Anth. adnatæ, bilocul. longitudinaliter præsertim apices versus dehiscent.

♂ Pollen magnum globosum hispidum, stylus filiformis basin versus pilosus.

Stigma conicum capitat.

Ov. liberum tubo calycis omnino inclusum, pilis niveis hispidissimum 1-loculare, 1-ovulat. stipitat. vel basin versus solidum sterileque. Ovul. pendulum ab apice loculi, foramen conspicuum hilum prope.

HAB. Mergue: *Jan. 9th, 1835.*

Nectandra decandra Roxb.

ELÆAGNEÆ.

This order agrees with Olacineæ in one remarkable point, that the calyx is analogous to an adherent calyx.

In Elæagnus, this is carried so far that dissection is absolutely requisite to detect it, and is accompanied with a development of a glandular disk, precisely similar to that of epigynous orders. The style too separates above its base.

There can be no doubt but that the Perianth is truly calycine.

The ovary is essentially simple, it has one vascular facicle that is prolonged upwards into the style, and which corresponds to the costa of ordinary leaves.

The placental suture is distinguishable, but merely by a line of different tissue, for no furrow exists as ordinarily happens. The stigma is also essentially simple.

The ovulum has the ordinary structure, its raphal face appears to correspond to the placental line above noted as indeed it should.

The stomata are very minute and are to be found only on the under surface. This is curious, one would have supposed that some compensating process would have existed, owing to the great obstacles to free ingress and egress of air presented by the scales, but unless these have some influence, I can see none.

These scales are maxima developments of facicled or stellate hairs, and they return to this state on the upper surface. The importance of these bodies is obvious from their general occurrence in the order.

The stamina are evascular.

. And so is the perianth except in the axis of the laciniae.

The greater permanence of the styles or stigmata is in addition remarkable from its being opposed to that which usually occurs. The parts next the axis being those most developed, and one would in reasoning a priori, imagine that the upper part of an organ which must be a continuation of the lower part, could not exist independently of this.

ELÆAGNUS.

I. *Elæagnus fasciculatus*, Pl. DXXXIX. Fig. II.

Fruticosa inermis, fol. lanceolatis mucronato-acuminatis utrinque sed subtus dense lepidotis, subrepandis, integris ramulisque novellis argenteo-lepidotis.

Fructibus in pedicellis lepidotis æquantibus varie numero aggregatis in axillis foliorum, vere racemosis, pedunculo brevissimo tri-binati-globosis, apice depressis et quasi unibilicatis, sinu conum brevem exserente, rubris, lepidotis.

PODOSTEMACEÆ.

PODOSTEMON.

Podostemon Griffithii. Pls. DXLI. Fig. II and DXLIV.

Plantula aspectu omnino fuci, axi verro nullo, e fronde orbiculari, lobato, in saxis semi-inundatis arcte adhærenti, viridi, lucido, somewhat slimy, constans, e disco promis-

cue flores numerosissimos exserens, sinubus lorum exceptis ?

Pedunculi brevissimi, squamis (bracteis) viridibus, distichis imbricatis, ovato-triangularibus, interstitio inter angulos 2 internos concavo et pedunculum amplexent. substantia demum angulum externum versus corneâ, primo cæteris partibus multo-viridioribus.

Spatha membranacea, sub anthesin subbivalvat fissa, dentius persistens sed demum labens. Per. nullum.

Stamen unicum, lateraliter in apicem pedunculi brevissimi situm, respectu frondis superficiei semper internum, respectu centro axisve externum ?

Filam. sursum arcuatum, carnosum, rubescens, basi utrinque processu setaceo-celluloso apice oblonga glanduloso summo apice recurvo auctum, apice bifurcatum, furca utraque extrorsum flexiusculâ, et stigma internum, vel externum quoad axin plantæ, amplexenti.

Antheræ cujusque furcæ, basi affixa, oblonga, bilocularis, fere didyma, loculis basin dehiscentiam subdivaricatis, lateraliter et longitudinaliter dehiscent. insertione obliquis, externo demissiore.

Pollen compositum e sphærulis 2 simplicibus lævibus, e sulcatis ? post immersionem etiam cohærentibus.

Filam evacuosum. Endothec. cellulis vix fibrosis.

Ovarium ovatum, acutum, breve stipitatum, stipite demum immutato, extus celluloso cæterum læve, 1-loculare.

Placenta centralis carnosae conformis, ovulis undique tertia, septo adnata ideoque utrinque alato-marginata.

Stylus 0. Stigmata 2 triangularia (angulo tertio infero) celluloso-papulosa, rubra sub repanda carnosae, internum quoad stamen majus.

Ovula oblonga angustiora quam in *P. Wallichii*, viridia, extus celluloso-papulosa ; tegumentum exterius (et unicum) celluloso, internis membranaceum, moleculas mobilis continens, omnino ut in *P. Wallichii* et nucleum componens.

Fructus capsularis ovatus, utrinque æqualis subacutusque, pedunculum brevem ipso duplo 3-plo breviorum terminans (stipite proprio non elongato, pedunculo duplo brevior.) Pedunculo demum nudo, lamina interior capsulæ, decoloratæ e cellulis transversa dispositis formata.

Capsula costis sub 16.

Semina oblonga, (immatura) omnino ut in *P. Wallichii*, Nucleus obovatus, parte attenuata supera, basin affixus.

OBS. The fronds of this plant are coriaceous, the cells of both cuticles? being oblong. The intermediate substance being white cellular and somewhat lax, it has no stomata.

Each axis of inflorescence is perfectly distinct, the frond moreover is entirely cellular, these axes appear at their bases to perforate the substance of the frond, and to be applied to the surface of the body over which the frond is spread, on detaching them, small round holes are left, perforating the frond completely, the same thing is visible on old plants, the frond of which appears to be a brownish thickish lobed film. spread over the stone, its surface being frequently perforated.

In very young flowers there is a central axis to the filament as well as to each of its crura, running to the connectivum. I can say nothing as to its vascularity, the filament and its crura are at this time very short, and not developed in the same ratio with the subulate processes.

The ovula at the same period are cellular oblong without any opening.

The capsules seem to be formed of 2 carpellary leaves, each of which has 5 costæ exclusive of 2 marginal ones of $\frac{1}{2}$ the size, by approximating these, we have the capsule 12-costate, the costæ formed by the margins of the carpellary leaves being duplicate and formed on both leaves. The dehiscence will I think be bivalvular, and septicidal. There is no septa attached to the parietes of the ovarium, but the placenta is certainly adnate to a septum, whose membranaceous margins project somewhat on either side.

2. *Podostemon Wallichiana*, Gr. Pls. DXLI, DXLII, DXLIII.

Planta minima, facie Hepaticæ cujusdam, acaulis (an vere) fronde depressa, planiusculi-lobata lobis sinuatis, sinubus omnibus florem exserentibus, coriacea, pallide viridescens, textura fuci, pede brevissimo textura crassiore magisque coriaceo, subdisciformi rupibus inundatis in rivulorum cursibus provenientibus arcte affixa.

Folia vera nulla, ast eorum loco frons, bracteoque pedunculorum basin cingentes.

Pedunculi solitarii uniflorum e sinubus loborum frondis origin. ducentes, maturato, 5-7 lineales, basin bracteis dense aggregatis alternantibus, fere textura frondis, coloris magis herbaceus, difformibus crassis cellulosis, intus peduncula prope canaliculatis, et eo appressis cæterum ascendentibus, inferioribus multo minoribus, axis vasculosa unica donatis.

Pedunculus e sinu spathæ tubulosæ cellulosæ apice multifidæ, et dilatatæ erumpens filiformis periphæria albidus, intus centrum versus ruber crassus filiformis, post anthesin cito attenuatus gracilis fere capillaceus, spatha androgyna.

Flos terminatis masculus semper externus quoad centrum frondis, ab initio spatha omnino tecta tuncque pedunculus curvatus, demum peduncul. elongato striato exsertus fit.

Perianth. nullum.

Stamina monodelpha, columna arcuatum, crassam filiform. basi utrinque processu celluloso initio rubro setaceo sæpe apicem versus introrsum vel stamini contrarie geniculat. filamentum brevius stipatus, tertio interdum brevius dorsali super addito paullo infra furcam filamenta.

Filam apice bifurcatum, propria brevia antheræ longitudine glabra ut commune læviaque.

Anth. basin versus affixa 1-bilocularis cuique furcæ introrsæ, longitudinaliter dehiscentes fere didymæ.

Pollen læve composita e sphæruis 2 connatis, et post dehiscentia nec separantibus.

Ovarium ovato-lanceolatum, eodem plana cum stamina

exsertum, sed semper internum, obsolete 8-costatum, sæpe læve.

Stylus nullus, stigma carnosum bilobum, subbilabiat. lobis conico-subulatis, interiore semper longiore et inter antheras flexo, saltem per anthesin.

Anth. loculis insertion. subobliquis, exteriore inferiore.

Ovar. nitidum 1-loculare, septis 2 longitudinalibus incompletis, rubris, et e foliis carpellariis 2 format. quorum unicum externum unum internum (ex situ stigmatorum.)

Placenta centralis ovato-conica, basi et apice tantum affixa, undique ovulis tecta.

Ovula carnosia viridia! oblonga foramine obsoleto.

Tegumentum extus, cellulosum crassum, extus papulosum obcellulos fluido repletos, intus tenuissime membranacea, moleculis minuti diffformes, mobilis ut etiam extus, copiosa continens, oblongum.

Capsula immatura in peduncula nudo gracila insidens, breviter stipitata. Spath. nempe caduca et stamen et processus setacea form ovarii 1-sulcat. nempe costæ cuique folio carpella 5 et 6 exeorum marginibus ortis ideoque duplicatis.

MONIMIACEÆ.

SARCODISCUS.

Sarcodiscus chloranthiformis, Gr. Pl. DXLV.

Flores fæminei solitarii vel in pedunculo bi-sæpius trichotomo bi-ternarii. Pedicelli lutei clavati.

Involucrum urceolare, colore pedicellum, apice quasi 4-fid. laciniis biseriatis, 2 exter, 2 inter, subimbricat. intus process. carnosus in unam connivent. deflexa, apertum in æstivat. abturant: prædat. Stam. 0.

Ovaria filling the involucre, not numerous, uppermost and largest arising from the wall of the urceolus, inner from fundus, opposite the outer smaller one. Ovaria conica subu-

lata, pressione subangulata pubescenti, 1-locul. ovul. 1, pendulum ex apice loculi anatropum. Stylus substigma inconspicuum.

Of this *Sarcodiscres*, I had only seen the fruit, at first, it is aromatic with the habit of *Chloranthus* in some respects, the ovaria strikingly remind one of *Anonaceæ*, its aroma is also *Anonaceous*.

Frutex.

Internodiis elongatis ad folii *articulos* incrassat. fol. oppositis exstipulatis, petiolis sub $\frac{1}{2}$ -uncialibus subterete! sulcatis, supra lamina elliptica, breviter cuspidato-acuminata, crenulata vel subdentato serrata-subcoriacea.

Venis 2-dariis, oblique arcuatis cum supera quaque conspicui punctis, cæterum reticulatis, venula centrali interveniar. 2-darium conspicua.

Fructus axillaribus, subcymosis, pedunculo partiale quoque subclavat. subuncial. apicem versus lutescens, discus magnus carnosus aureus subaurantiaceus, basi inferne planiusculus, marginem versus intus cicatrisubus, circa marginem sæpius lobulosus, lobulis apice ovariis vel perianthii lapsu cicatrisat. vel etiam in disco subirregulariter sitis.

Pedicelli fructigeri carnosi aureo-aurantiacei.

Baccis *anguste ovatis*, purpureo-cæruleis, basi nudis, apicem styli reliquis inconspicue gerent, uniloculares, 1-sperma carne pallida, cellulosa.

Semen, pendulum, magnum, forma fructus; tegument. chartaceo-membrana: cum fructu secedens, hinc apicem areolatem (micropyle).

Raphe lata, generally conspicuous as also broad, chalaza fucescent from coming way with the embryo.

Albumen copiosum carnosum extus præsertim supra medium viridescens, apicem prope albo-areolatum (situ radicis).

Embryo albus leviter curvatus subaxilis in album. dimid. supero.

Radicula longa clavata supera. Cotyledones ovatæ foliaceæ venosæ.

Sapor et odor contus piperaceus.

Perhaps in most of its characters it is Daphnaceous, indeed the leaves are not unlike those of *Jenkensia*.

1. Plant reduced $\frac{1}{2}$ except fruit.
2. Fruit back view.
3. Ditto front.
4. Long section to expose the seed, *a* hilum, *b* raphe, *c* chalaza.
5. Long section through, the body of the seed, *a* tegument, *b* albumen, *c* embryo.
6. Seed detached back view, *a* funicle, very short, *b* raphe, *c* chalaza.
7. Same, as it generally separates with only a part of the tegument and raphe, and chalaza.
8. Ditto to shew the areola marking the site of the root.
9. Embryo.
10. Ditto one Cotyledon removed.

Caules articulati, articuli incrassates, fol. lanceolato-oblonga, petiola acuminata glaberrime coriacea supra lucida, subtus glauca, basin sub 3-venia, intra veniis reticulatis, concaviusculis.

Spicis terminalibus pendulis compositis luteis, divisiones frondiformi reniformes, breviter stipitati, margine anteriori fissæ floriferæ.

Flores dioici masculi tantum visi, intra fissuram recondit pilisque obsiti, uniseriati.

Flos masc. e stamen 1, filamentum crasso. Antheræ terminales biloculares longitudinal, dehiscent.

Aromatico pungens.

HAB. Malacca at Ching. Scandens in Abor. Nhingull. Generally distinct from Piper; in the e bracteate flowers as in the inflorescence.

Habitus Piperis.

CHLORANTHACEÆ.

CHLORANTHUS.

Chloranthi sp. Pl. DXLVII.

The habit is that of Piperaceæ, the wood consists of a continuous system with many medullary rays, the vessels are rather small, and the surrounding fibres punctuated. The pith abounds in amylaceous? granules.

The external fibrous system is in juxta position with the bark and consists of several fascicles of irregular sizes, while the space between this and the ligneous system is filled up by very soft cellular tissue.

The cells of the cutes are sinuous, that of the under surface being alone stomatose.

The whole appendages of the axis are disposed in a regular binary manner, the flowers are regularly and decussatingly opposite.

The number of anthers I take to be 4, the two lateral ones being distinct, the intermediate lobe bearing two anthers; all these are quadrilocular, at least in the young state the upper loculi being much the smallest.

The ovarium is simple notwithstanding that the style can scarcely be said to be oblique, the stigmatic cannal is distinct.

The ovulum is attached to the inner side with respect to the axis and towards the summit, it is antitropous. The chief enlargement of the ovary after fecundation takes place towards its base, hence the scar by the falling off, caused of the filament appears to be carried up, until it becomes nearly terminal?

The two coats of the ovule are distinct and the chalaza conspicuous spreading over the base of the nucleus, which adheres slightly to the inner integument.

It is the inner portion of the outer which subsequently becomes the drupaceous coat, hence the micropyle should be visible on it when mature.

The excavation formed within the nucleus is lined by an albuminary membrane excessively fine, it is in this that the albumen is formed. The embryo is of late appearance.

The micropyle becomes indurated and somewhat mamilliform; and is at this stage, which is before the appearances of the embryo, green.

Fructus: ovati utrinque obtusi, spicati, basi bractei squamiformi herbacei: coloris suffulti subbacati miniat.

Pericarpium crassiusculum carnosio-fungosum, intus parce venulosum, apice stigmatis reliquis coronatum, et obliquusculum? 1-loculare.

Semen unicum pendulum forma pericarpium sed utrinque acutius.

Tegument. album, durum subosseum, membranes 2 quarum exterius tenuissime membranac. interius induratum.

Corpus album carnosum, succosum, hujus cavitatem omnino replens, albumen.

Embryo minutus, in apice albuminis locatus, albus, subglobosus, superne bifidus.

An per 4 sepal, staminque hypogyna?

Habitus Cissi.

BÆHMERIA.

1. *Bæhmeria melastomoidea*, Gr. Pl. DLXIII. Fig. II.

Basi decumbens et suffrutecosa, scabra, pedalis vel bipedalis.

Caulis ruber, angulatus, subanceps, pilis scabris lineatum dispositis asper, basi subteres.

Fol. (floralibus exceptis) opposita. linearia vel lanceolato-linearia, acuminata acutiuscula, breviter petiolata, tri-venia, marginibus hyalinis pilis ascendentibus scabris, albopunctata, venis secundariis transeverse anastomosantibus.

F. floralia alterna, infima subopposit. Petioli rubri. Stipulæ *f.* caulinarum interpetiolares, demum deciduæ floral. solutæ, cuneato-ovatæ scariosæ, fuscæ.

Flores monoici pauci in axillis aggregati, bracteis minutis suffulti.

Masculi pedicellati, et præsertim superiores fæmineis numerosiores, floribus fæmineis comitantibus multo magis *tardiores*.

Cal. 4-5 sepalus, sep. æstivatione valvata navicularia apice intro fracto triangularia trianguli basi elevata carnea pilis uncinatis parvis pilosa, marcescentia, alabastra cyathiformia.

Stam. totidem his opposita æstivatione introflexa, demum elastica dessilientia. Filam. carnea subulata antica rugosa et longitudinaliter striato-sulcata. Antheræ basi affixæ, biloculares longit. lateraliterque dehiscentes membranacæ, loculis septo incompleto bilocellatis. Pollen album globosum læve. Rudiment fæmin centrale conicum.

Fæminei sessiles. Calyx herbaceus emarginatus sinu lato

compressus, postice convexus, antice centro alatus, hirtus. Ovarium unicum ovatum acuminatum, 1-loculare, ovulum 1, erectum foramen apicula. Stylus brevissimus. Stigma maximum, incrassatum, pilis cellulosi simplicibus hispidissimum, deciduum, fasc. vasor. unicum tenue.

Fructus calyce ampliato albo 3 rarius 4-alato inclusus, calyce postice convexiusculo, 4-sulcato, rarius hinc alato alæ utrinque 1-sulcato, emarginato, sinu angusto, antice medio alato, et corolla papilionacea now male referentem, glandulosus et hirtellis, ob obovatus, ater nitidus lævissimus stylo apiculatus.

Semen unicum erectum fructu conforme. Testa subcoriacea, e cellulis sinuosis conflata, tegument interius tenue membranoso-cellulosum albumen carnosum-farinaceum.

Embryo axilis rectus albus inversus. Radicula conica.

Cotyledones rotundatæ, faciebus latioribus seminis parallelæ. Plumula inconspicua.

HAB. Upper Assam. Suddyah: *July 6th*, 1836.

The ovula have two coats, the outer of which forms the tegument of the seed, the sinuous cells are developed from above downwards, this always separates with the pericarp. The second integ. subsequently becomes united to the nucleus and finally disappears.

The albumen is developed within a very fine membrane formed with the cavity or excavation of the nucleus. It is in an early stage attached to the base of the nucleus. The embryo appears early.

This forms an exception to the statement of Schlechtendal, that opposite leaves are never disjointed, male flowers articulated on the apices of the pedicels. The pedicel being in one species persistent.

CHAR. GEN. alabastra masc. cyathiformia. Sepalorum apices introfracti triangulares, basi elevata carnosæ, cal. fæm. integer. evalvis emarginatus, fructus 3-alatus, alis lateralibus majoribus. Fructus stylo persistente apiculatus.

Vix differt a Bæhmeria.

Suffrutus, foliis caulinis oppositis, 3-veniis, stipulis interpetiolaribus, floralibus alternis. Flores in axillis aggregate utriusque sexus mixto.

11. Embryo.

Folia carpellaria cum sepalis alternant. signum est oppositionem staminum sepalis minoris valoris esse signum est etiam that whatever the number of series of stamina may be, that the ovaria will rather have relations with its sepals than with the innermost series of stamina.

MORUS.

Morus acidusus Gr.

Frutex ramosus virgatus 4-6 pedalis ramulis novellis brevibus folia fructiferis.

Fol. breviter petiolata indivisa vel bi-trilobata ovata, caudata, acutissima cum mucrona argute serrata, serraturis mucronatis interdum duplicatis teneriuscula, tactu retrorsu scabra, glabra, basi 3-venia, venis secundariis arcuatum nexis, primariis lateralibus externe tantum secundariferis intervenis quam maxima reticulatis, cauda integerrima.

Petoli sub $\frac{1}{2}$ unciales, stipulæ cuducæ.

Gemmæ axillares, sæpissime ad latus peduncolor. semperque posticæ vel interiores quoad ramum fulcientem.

Fructus; axillaris in pedunculis, subnutantibus, linearibus pubescentibus, oblongis aggregatis rubris, sapore mori albæ sed multo magis acidiora, lobato-rugosa, stylis stigmatibusque persistentibus quasi echinata.

Calyx fructus carnosus, sepala 4, cucullata, carnosæ colorata.

Pericarpium liberum ovatum, verticaliter compressum stylo stigmatibusque persistentibus his sphacelatis terminatum, obliquum, tenuiter baccatum.

Semen unicum ovatum compressum, pendulum pericarp. adhærens. Testa ossea fragila.

Tegument. interius albumen includens tenue membranacea, albumen copiosum, carnosum album.

Embryo curvatus, vix axillis periphericus, approximatus albus.

Radicula longa, supera, teres, cotyledones subæquans.

Cotyledones cordatæ foliaceæ planæ, faciebus angustis seminis oppositæ quoad axi plantæ incumbentes.

Plumula inconspicua.

Micropyle inconspicua hilum prope.

HAB. Cheikwar in sylvis, communis est: *April 8th*, 1836.

Ficus.

1. *Ficus sideroxyliifolius*, Gr. Pl. DLI Fig. 2.

Arbuscula cortice grisea fol. spathulato-obovatis ascendent. medium supra patentibus coriaceis subtus subferrugineis fructibus axillar. binis (pedicell. petiolis paullo excedent) obpyriformi turbinatis.

HAB. Malacca, Tanjong cling in arenis vel terrest. vel Epiphytic.

2. *Ficus indica*.

Arbor vasta indefinite extendens ope supports e ramis omnibus primarii emissis. Corona densa formosa, 100 pe-

dalīs. Rami inferni horizontali extendentes, superiores oblique a decedentes.

Ramuli crassi compressi. Petiolis biuncialis, complanatis, obsolete canaliculatis.

Folia elliptico-oblonga, breviter obtusque cuspidata subrepanda integerrime glabra, coriacea, basi subtrivenia, venis secundariis arcuatim nexis, interstitiis reticulatis, plerumque vena additoria central. reticulationes inferne parvæ.

Gemmæ, conico, subulatæ, $1\frac{1}{2}$ uncialis, squamæ velutinæ. Vernatio involuto-convoluta.

HAB. Bengal, near villages.

Obs. The glory of the genus as well of the Indian Sylva. There is absolutely no limit to this tree, which may either continue simple, or by the destruction of the part of the branches between the support and the trunk, it may become subdivided.

Roxburgh calls the leaves ovato-cordate : is this, therefore, his plant ?

3. *Ficus glabrus*.

Arbor magna, trunco parum sculpto, ramis patentissimis vel ascendentibus, e radiculosis.

Internodiis abbreviatis. Petiolis subcomplanatis.

Foliis alternis oblongo, ovatis integris coriaceis, apice rotundato obtuso, glabris lævibus.

Venis secundariis distinctis lutescentibus arcuatim nexis, interstitiis reticulatis venis additoriis plerumque interjectis reticulatione inferne minima.

Stipulis, uncialibus conico subulatis.

Fructibus axillaribus sessilibus, binis, aurantiaceis lævissimis, oblongo-rotundatis, umbilico minimo.

HAB. Assam, Gowahatti in silvis.

4. *Ficus obovatus*, Pl. DII. Fig. I.

Arbor. Rami annulati ramulique angulati.

Petiolī breves supra canaliculati et complanati.

Gemmæ conico subulatæ $\frac{3}{4}$ unciales.

Fol. obovata obtusa integerrima coriacea, venis additoriis secundariis subæqualib. intro marginalibus distinctis, reticulatii inferne minimis, stomatosa portios reticulas excedens.

Fructus sæpius binati aliquando abortionem solitarii, sessiles in axillis subgloboso apice depressa, umbilico squamis imbricatis 3, summis cum calyculicinis squamis alternant. internis introflexis, basi calyce triphylo imbricato cincto, superficie verrucosula.

Calyx initio receptaculum omnino obtegens.

Habitus arboris Artocarpa integrifolia, quoad gemmæ floriferæ et foliatione accedit Guttiferis quibusdam.

Obs. The consideration of the scales seen in such various situations on the parts of fructification of *Ficus*, would lead us to suppose, that the receptacle is formed from the cohesion of a vast quantity of bractes. In the usual acceptation; the bractes must be supposed to be latent, otherwise the flowers will bear no relation to the usual parts. In this species in the earlier stages the bractes exceed in bulk the size of the receptacle and this in still earlier stages does not, I dare say, exist. The matter will be at once set at rest if any species are found the flowers of which have a determinate relation to the bractes or scales.

HAB. Assam.

5. *Ficus elastica*, Pl. DLII.

An immense tree, with the trunk richly sculptured, and supports thrown out from the bases only of the principal branches, which spread out horizontally.

The young branches are angular, the scars of the leaf buds which are terminal, are very oblique, scales, stipulæ of anthers, large membranaceous, colored.

In young specimens the foot stalks are flattened, and furrowed above.

Leaves elliptical or ellipto-oblong cuspidate, acumina very

entire, very smooth coriaceous, midrib large whitish, other veins tolerably equal, parallel, the larger ones connected by a distinct intramarginal vein, towards which the parallel veins become evidently reticulate.

Flowers (young fruit) compound axillary sessile in pairs, surrounded at the base by a fleshy cup, closed at the apex.

6. *Ficus affnior* Pl. DLIII.

Arbor crescentia et habitu omnino Fici affinis.

Petiol $2\frac{1}{2}$ uncialis basi incrassato supra canaliculata.

Fol tremule alterna ovulo-oblonga vel subelliptica plus minus repandum subito cuspidato acuminata, coriacea utrinque glabra venatio Peepuli, reticulationes inferne minutissimæ. Gemmæ brevissimæ conicæ.

Fructus in spicas nudis densiusculis disposit sessiles.

Fructus; bini sessiles in axillis, sæpe ob foliorum dejectu spicati, globoso-turbinati, punctis subcavatis lutescentibus notat. basi calyculo tridentato cincte. Umbilico clausa, squamis extimis ternis.

This description refers to the real *jooree* or *Ficus affinis* of Gowahatti.

The growth is exactly that of Peepul and Jooree it is a lac tree; it differs from Peepul in the shape of the leaves and want of tail, from Jooree in the coriaceous nature of the leaves, their shape and sudden cusps.

The habit is similar to that of the Peepul, for which the tree may easily be mistaken, the shape and chartacious nature of the leaves are however obvious distinctions.

This tree has the same growth and sculptured stems, the net work its roots form is often extraordinary; and in one instance I have seen a large tree entirely surrounded with a flattened-out root. Such trees always soon die: attempts are sometimes made to throw down a continuation of the woody and cortical growth.

7. *Ficus peepul.*

Arborea, trunco composito, interdum puro reticulato, cortice alba glabra.

Ramuli teretiusculi, gemmæ semuncialis subulatæ.

Folia longe petiolata, petioli teretiusculi apicem versus canaliculati basi interdum sub $\frac{1}{2}$ torti.

Fol. deltoidea, longe cuspidato-acuminata, fere caudata, lateribus basi rotundata undulata chartacea basi sub 5-venia venis secundariis distinctis et distincti arcuatum nexis secundariis 4, infimis externe ramosis, minute reticulata subtus.

Fructus in ramulis foliis expers, bini et sessiles in axillis, approximatus ita ut spicum mentiunt. turbinato-globosa sunt verrucioles albis, viridibus cæterum glabris, basi calyculo ternato inconspicuo.

Umbilicus omnino clausus sequamis tribus externis alternantibus cum calyculo, interioribus plurimis introflexis.

HAB. Assam. Tezpoor.

The trunk varies much: generally several and all united, and really arborescent, occasionally clasping large trees, when are then reticulate.

8. *Ficus* sp. Pl. DXLIX. Itinerary Notes, p. 111, no 145.

7. Longitud. section of a fruit.

HAB. Bootan.

11. *Ficus papyrifera*, Gr. Pl. DLIV. Fig. 11.

Arbor mediocris, trunco albo parum sculpto, ramis nutantibus, novellis flexuosis.

Foliis alternis elliptices longe cuspidatis obtusis chartaceo. coriaceis integerrimis, venis secundariis tenuissimis arcuatim nexis quam additorum vix magis conspicuis vena intramarginalis distincta.

Fructus axillaris, solitarius globosus, pallidus, pomi parvi magnitudinem, umbilico squamulis minutis clausa.

Stipulis, subulatis viridibus brevibus.

Cortex tenacissimus.

IIAB. Assam. Gowahatti in sylvis collinis.

12. *Ficus pellucido-punctata*, Gr. Pl. DLIV. Fig. I.

Arbor robusta, breviuscula, corona densa, lata.

Ramuli compresso-angulati.

Petiol. semuncialis, profunde canaliculat. fol. obovata, vel sub ovata, obtuse cuspidato-acuminata integerrima, pellucido-punctata venis indistinctis, exceptis secundariis, reticulatione inferne magnis.

Fructus, rubescentis sessilis, binati, abortu solitaria subrotunda basi tribracteata. umbilico, semini aperto, cerasi parvi magnitudinis glabr.

This has the usual epiphytical growth.

HAB. Assam Gowahatti in sylvis.

13. *Ficus aurantiaceus*, Gr. Pl. DLIV. Fig. II.

Ficus scandens radicans caulis compressis utrinque centro sulcatis, ramuli alternantes elongati, Gemmæ inconspicuæ subulatæ.

Foliis oblongo-ovatis brevi petiolatis obtusis integris vel obovatis basi attenuatis, coriaceis subtus pallidis subpilis with conspicuous white often binary spots (stomata) tactu aspera verruculis plurimis albis petiolis pilosis.

Fruits (anthodium) axillaribus from a short knob-like branch solitary pendulous obovate subpedunculate (pedunculis about $\frac{1}{2}$ inch long) at the base of its stalk with 3 subcordate bracteate scales, and a mamillate umbilicus at the apex; at first the colour is orange, then deep blackish purple when it is deliquescent.

Flowers of both sexes long-stalked, stalks white. Anth. oblong, lilac or white and transparent. Stigma bipartite acute, style oblique seed pendulous oblong with a thick white margin especially at the micropyle. Inner tissue or membrane elastic, albumen sub. 0, radicle moderata.

HAB. On trees, Malacca, between Rhim and Ayer Punus.

14. *Ficus mangiferifolia*, Gr. Pl. DLV. Fig. I.

Arbuscula corona densa, habitu mangiferæ ramuli compressa.

Petoli 2-3½ unciales, graciles subcomplanato supra sulcata.

Folia lanceolato-oblonga, repanda, cuspidato-acuminata, acumina semi-torto, chartacea glabra venatio ordinaria reticulationes inferne minutissime areolis punctis pellucidis 2-3 distinctissimis, sublente.

Gemmæ ovatæ, squamæ coriaceæ brunneæ.

HAB. Assam. Beylottah.

15. *Ficus intermedus*, Gr. Pl. DLVI. Fig. II.

Arbor magna.

Cortice ramorum cinerea. Ramuli petioli foliaque subtus scabrelli.

Petoli teretes supra lineali 1½ lineales. Gemmæ minimæ conico subulatæ petiolis breviores.

Fol. alterna oblonga vel obovato-oblonga basi sæpe inæqualia longe et obtuse cuspidata integra chartaceo-coriacea supra lævia glabraque interveniis subconvexis, venatio secundar. valde distincta arcuatim nexæ additoria subnullæ, tertiariæ grandes, direction sæpius transversæ reticulationes ultimæ minimæ.

Fructus pedunculat. sæpius (abortu) solitarii in axillis pedunculis petiolo paullo longiorib. basi pluri-squamati scabro-hirti, uti superficies fructiis globosi, verrucis irregularibus ochroleucis, umbilico subaperto succus fere aquosus cortex tenax

16. *Ficus millingtonifolia*, Gr. Pl. DLVI. Fig. I.

Arbuscula.

Ramuli cinereo-ferruginei compressi.

Petioli concolores puberulæ complanati supra canaliculati semunciales.

Gemmæ subulatæ, acutæ. Folia interdum subopposita obintermod. abbreviationem brunneæ, puberulæ.

Fol. obovato-oblonga subrepanda cuspidato-acuminata subcaudata, integra chartaceæ utrinque glabra, supra sublucida, venatio ordinaria secundariæ subdistincti nexæ, intervenia harum supra clavata, reticulationes inferne majusculæ.

Obs. *Ficus caudatæ* affinis, sed distincta, verruculis nullis, petiolis complanatis, foliorum forma, et acuminatione, et glabratione, et habitu.

HAB. Assam. Beytollah.

17. *Ficus caudata*, Pl. DLVII. Fig. I.

Scandens in arboribus ramuli verruculis uti petioli exasperat. subteretes.

Petioli compressi supra canaliculati semi torti.

Fol. oblonga magnitudinem varii, 2-4 uncialia vel etiam fere pedalia, integra, subtus tactu aspera, subito longeque cuspidato-caudata,

Venatio ordinaria, interveniis plerumque subullatis, basi subtrivenia reticulationes inferne minimæ.

Gemmæ breves bilineales brunneæ, uti petioli ramulique.

HAB. Assam. Gowahatti.

Distinct, especially on account of the compressed not flattened petioles.

18. *Ficus longipes*, Gr. Pl. DLIX. Fig. II.

Frutex scandens.

Ramuli compressi, folia ovata coriaceo-chartacea, integra subacuta, venatio-ordinaria, reticulation infra minima.

Gemmæ conicæ breves, 2 lineales.

Fructus, axillares, solitariæ abortu in pedunculis, uncialibus petiolos $\frac{1}{2}$ excedentibus apicem bracteatis, ovato-globosa, cerasi parvi magnitudine, umbilico annulo cincto, clauso, aurantiaceis, glabra, pedunculi infra incrassata ascendentes.

Cicatrix inflorescentiæ secundæ distincti in axillis.

HAB. Assam. Gowahatti.

19. *Ficus sclerocarpa*, Gr. Pl. DLVIII.

Arbor

Pubescente hirta. Ramuli robusti. Venation of the corolla perfect, monopetalous.

Petiolis rotundatis. Folia longe petiolata cordiformi-orbicularia breviter et obtuse cuspidata remote et inconspicue serrata, utrinque hirta basin 5-venia, sub-chartacea venæ secundariæ distinctæ minutæ margine attingentes, tertiariæ secundarii intermediarum arcuatæ, cæterum transverse varie reticulatæ.

Fructus: maximus diametro 3-4 unciali late turbinati longe pedunculati, hirta umbilico maximo, aperto ore squamato, dura inedules.

Pedunculo clavato apice squamigero.

Section different, but allied to Roxburgh's *Ficus macrophylla*.

HAB. Assam Gowahatti in Sylvis.

20. *Ficus histipulatus*, Gr. Pl. DLIX. Fig. I.

Frutex erectus, 6-8 pedalis. Rami robusti, corpore ligneo parco, medulla ampla.

Fol. alternis, petiolis rubris, uncialibus supra lineato-canaliculatis, oblonga basi subcordata acuminato-cuspidata repanda, pubescente hirta supra tactu scabra, venatio ordinaria duobus infimis secundariis basi approximatis, ideoque, fol. trivenia, venis rubro-tinctis, vernatio conduplicata.

Stipulæ membranaceæ, stipulis urticeis similis duo persistentis.

Fructus: bini abortive solitarii in axillis, pedunculati, pedunculis petiolo 4-plo brevioribus, medium versus articulates ibidemque tribracteatis, turbinata rubra, punctis irregularibus albidis, umbilico annulo obsoleto cinct.

HAB. Assam Tezpore sylvis squamis clauso.

This belongs to a very different section characterised by its large medulla, leaves hairy on both sides, with membranous distinct stipules, and terrestrial habit.

21. *Ficus oppositifolia*, Gr. Pl. DLX.

Frutex arbusculoideus robustus.

Ramuli teretes crassi medulla magna contracta fistulosa scabrida.

Folia opposita petiolis vix uncialibus, subteretibus oblongis basi cordatis novella brunneo-pubescent. obsoleto dentatis cuspidato-acuminatis, tactu utriusque scaberrimis venis omnibus infere prominulis.

Gemmæ mediocres, conico-subulatæ, stipulæ membran. caducæ, discretæ binæ.

Fructus in racemis axiliariis abbreviatis, squamatis sæpius binatim aggregat. pedunculis 2-3 linealibus, globoso-turbinalis, subscabris interdum subcostata costis squamis circum. umbilicum respondentibus basi calyculo trisepalo cincti, apice squamato, squamis carnosius pluribus umbilicum claudentibus, an affinis *F. laminosæ*.

In aquosis ad margines sylvarum.

HAB. Assam, Gowahatti : *December*.

This species comes very near to *Ficus laminosa*, especially in the stipulation and shape of the leaves, it is the only one with opposite leaves yet known ; Jenkins tells me that *Ficus carica* has been grafted on it.

I consider this genus to prove absolutely that stipulæ are mere scales of buds, and that they are not necessarily double organs.

In this species if they are double organs, we must assume their coalescence, of which there is no trace.

The fruit of *Ficus* is entirely analogous to those *Compositæ*, whose receptacle is quite naked, the outer ones being involucre, and as it were carried up and closed over the receptacle.

22. *Ficus rubifolia*, Gr. Pl. DLVII. Fig. III.

Scandens radicansque hirsuta scabra.

Folia cordato-ovata indivisa vel tri quinque loba more Rubi vel Hederæ.

Squamæ persistentes duæ membranaceæ.

Fructus longe pedunculata ovato unceolato hirsuta apice depressa.

Pedunculi uncialis petiolas excedentes, apice bracteati.

F. heteroplyllæ accedens.

HAB. Assam Gowahatti.

23. *Ficus apocynoides*, Gr.

Frutex repens in arboribus caule, petiolis, foliisque subtus pubescent.

Petioli breves $\frac{1}{4}$ uncialis supra plani.

Folia opposita ! lanceolata, vel sæpius lanceolato-ovata obtuse acuminata, integra chartacea, supra glabra. Venatio ordinaria, secundariis distincti nexis stomatose portion in excess.

Ciliæ inter petiolares distinctæ.

Procul dubio igitur Apocynea vera.

HAB. Assam Tezpore in arboribus.

24. *Fici* sp. Pl. DLVII. Fig. II.

HAB. Bootan.

HAB. Bootan.

ARTOCARPUS.

1. *Artocarpus cuspidatus*.

Arbor.

Ramuli robusti ferrugineo-hirti, uti petioli: gemmæ, foliaque subtus ad venas.

Petioli teretes subunciales.

Fol. obovata vel sæpius obovato-oblonga, obtusissimo uno etiam sæpius emarginata, integra, minora interdum apice dentata coriacea, dura, scabra, v. 2 dariis obliquis rectiusculis, intra marginem arcuatum nexis v. ven. intromarginal. commun.

Fructus axillaris subsessilis, globosus irregulariter horizontalis, covered with innumerable scabrous long points from conical angular bases, from the irregular way in which these points are disposed, not all radiating from a common surface, the fruit would look outside as if it were composed of many concrete capituli.

When ripe if opened or torn across, it separates into a globose receptacle densely crinite; these crina are the styles of the abortive pericarpia, few of which are at all enlarged, still fewer seed-bearing. The rest is fleshy, while the concrete perianths each presents a channel occupied previously by the style, each perianth ends in the point before mentioned.

Fruitlets large, oblong with an apiculus, baccate of an agreeable subacid flavor, inner layer membranous and very thin, to this the pulpy tissue is attached.

Pericarp relatively small, oblong, whitish, with an obsolete longitudinal line along both faces, a chartaceous thickish white covering distinct from the membranous one to which the baccate part is attached, seed pendulous oblong brown with a $\frac{1}{2}$ complete raphe, beautiful and palmately branched at the chalaza, the branches all converging over micropyle. Tegument 1, thin and membranous.

Albumen 0. Cotyledons fleshy plano-convex, radicle very short next the hilum.

HAB. Malacca Verupha Aloor Gagal of the Malays, *A. echinatus* Roxb. *Tampooni*.

2. *Artocarpus*, sp.

Arbor humilis, corona patento, ramulis petiolisque plumbeo-viridibus velutinis, stipulis ovatis, *parvis*, fol. oblongis basi oblique cordatis repandis breve acuminatis subintegra, supra glabris, subtus reticulatis scabrisque. Stigma truncatum, subtrigonum obtuse pervium.

Ovula 00, placentis axilibus carnosiss affixa anatropa, sessilia, erecta vel ascendentia.

HAB. Malacca.

Obs. I see no reason why this genus should not range in or near Lythraræ, in which apetalous forms are not uncommon, and which indeed is pointed out by the frequent minuteness of the petals, and the coloration of the calyx. The situation of the stamens may be an objection, but this is perhaps explainable. The structure of the seeds is the same, and altogether the sum of the characters is Lythraceous.

SCEPACEÆ.

Scepacea.

Ramuli teretes albidi novelli subangulati.

Folia alterna, stipulæ deciduæ, petiolus sub 4-linealis utrinque incrassatus, lamina dependens ut plurimum leviter conduplicata oblonga vel sublanceolata mucranato-cuspidata integra, long. 4-4½ unc. lat. 1-7 lin. carnosissimo-subcoriacea, venis secundariis arcuatim nexis, interveniis reticulatis, the reticulation is most evident underneath.

Spicæ axillares subbiunciales, pubescentes in pedunculum abbreviatum insert. ideoque racemosæ, racemis interdum plus quam 1. Bractææ lanceolatæ brunneo-puberulæ subbinæ ad basin spicæ cujusque, initio imbricatæ. Bracteola pallidiora velutina minuta sub florem quemque concava.

HAB. Merguc. Conspicua obamssas florentiæ densas, contuse adorem resinosum piperaceum effundit.

2. *Astropetalum* sp.

Arbor excelsa, fol. sæpius alternis ad apices ramorum confertis, petiolatis oblongo-lanceolatis, obtuse acuminatis integris subrepandis marginibus cartilagineis, nervis secundariis distinctis, nervo primario angulum valde obtusum formantibus.

Paniculis terminalibus foliosis patentissimis multifloris, floribus pallide lutescent. subodoris, obmassas longe conspicuis.

Cal. tubo brevi, limbo 5-fido, laciniis rotundatis æstivatione imbricatis.

Cor. 5-petala, petalis hypogynis, lineari-lanceolatis reflexis

unguiculatis unguibus gynophora adnatis. Petalis post anthesin ampliatis foliaceisque!!!

Stam. 5 hypogyna basibus versus alatis et gynophoro adnatus petalis alternant. Parte adnate quasi sphacelato Filam. libera subulata basi dilatata petalis breviora. Anth. biloculares longit. dehiscentes bases versus affixæ, introrsæ Pollen oblongum ellipticum læve albidum. Stylus brevis filiformis subobliquis, nec vere apiculis. Stigma capitat. medio foveolat.

Ovarium gynophoro insidens ovatum 1-loculare, 1-ovulatum. Ovulo vere pendulo, lateraliter et supra basin loculi inserta, funiculo brevi tenui sustentum. Foramen hilum prope loculi fundum aspiciens.

De perigyne si stamina hujus ordinis auctores pessime judica verunt. In omnibus generibus, quæ examinatione subjeci, stamina evidentis et omni sensu hypogyne. Hoc genus intermedium est cum Syndesmis (sp. 2.) no. 675, cujus gynophorus longius stipitatus et stylus omnino obliquus.

BUCHANANIA.

Buchanania subobovata.

Foliis subobovatis, paniculis folia excedentibus albis, floribus 4-5-meris, stam. basi effætis.

Rami teretiusculi, ramuli virides.

Folia alterna apices internodiorum vel ramulorum subconferta, exstipulata, petioli basi incrassati, subuncialis, lamina subobovata, long. 4-5 unciali, lat. $1\frac{1}{2}$ fere 2 unc. coriacea concaviuscula obtusa interdum emarginata, margine maturiorum sæpe undulato-crenata, v. secundariæ arcuatim obliquæ convexæ, v. aliis anastomosant. paullo minoribus, subtus venatio depressa et minus conspicua. *Vernatio conduplicata.*

Paniculæ axillares, foliis longiores obfolia conferta quasi thyrsus terminalem formant.

Pedunculi subspithamæi albi compressi rami secundarii

curvatim ascendentes an semper ultimæ cymoideæ vel racemosæ paucifloræ.

Flores minuti albi 4, sæpius 5-meri, odore ingrato, pedicelli breves clavati. Sepala 4-5, semi-ovata unico extimo minuta. Petala æstiv. imbricata totidem alternant. oblonga, patente reflexa obtusa.

Stamina petalorum numero dupla petalis $\frac{1}{2}$ breviora hypogyna subæqualia, filamenta alba subulata. Antheræ erectæ longitud. filamentorum magnæ, obtuse sagittatæ, pars sagittati alba effæta! Pollen aureum.

Cupula carnosæ alba denticulat inter stamina et pistillum, hoc ex dimidia parti obtegens. Ovarium stipitem crassum brevem terminans subovatum. Styli 4-5 parce pilosi, stigmatibus totidem subcapitata.

Potius ovaria 4-5 petalis opposita, parce pilosa 1 tantum fertile, sterilia interne sulcata, in stylos crassos, stigmata capitato-terminalis attenuata: fertile ovatum 1-loculare, ovulum 1, terebinthacea, nempe pendulum e funiculo basi loculi affixo, foramen inferne spectans, stylus crassior brevior, stigma subsimplex.

It is remarkable, that the stigmata of the barren ovaria are alone developed, and alone shew the usual browning of fecundation! Can therefore be any communication between these ovaria and the ovuliferous one.

MANGIFERA.

1. *Mangifera lagenifera*, Gr. Pl. DLXVII. Fig. III.

Fruit gourd-shaped, smooth glaucescent discharging when wounded a black varnish, smell fetid, fleshy, entirely traversed by innumerable fibres, besides which it looks just as if it were minutely veiny reticulated.

The inner fibres are as thick as twine, and cutting through them is like cutting through twine.

Drupe entirely covered with innumerable fibres, lanceolate, ovate subæqualiter fibro-leathery.

Tegmen of seed separates with it, this on one side is black, thickish and coriaceous and sticks to the seed, but still is separable, on the other side it is fine membrano-chartaceous.

Seed erect, oblong lanceolate; one side, *i. e.* that to which the black part of the tegument adheres, presents an irregular surface, the other is smooth and traversed by the straight commissure of the cotyledones, the other is traversed by an irregular commissure.

Radicle stout short, a little above the base, each cotyledon is oblique at the base, and each has half the surface wrinkled, and half smooth.

In this, one cotyledon is longer than the other.

a. Auricle, white, *b* radicle; *c* root. *f* smooth, the other marks denoting rough.

HAB. Malacca. This is a pentandrous Mango-flowered large tree, with a round crown, high trunk, branched above, and spatulate obovate leaves. The Malay name is *Langoot*.

It is equally well distinguished by its lageniform fruit, by the rugose smooth cotyledones, calyx auricled outside below the radicle.

In the following (Beenjai) the auricle is confined to the larger cotyledon.

2. *Mangifera cæsia*, jack.

Arbor excelsa, habitu foliatione quodammodo magnolia-cearum quarumdam.

Fol. cuneato-obovata, summa ad apices ramulor. conferta conduplicato-oblonga base attenuata acuminata apice rotundata coriacea venis 2-dariis distinctis.

Paniculæ thyrsoidæ, amplissimæ terminalis ramulis ultimis cymoso-umbellatæ. Flores polygami.

Masc. Sepal 5, 2 interioribus longioribus. Petala totidem erecta, apice patenti-reflexa (ideoque corolla videtur hypocraterif. tubo elongato) lineari-spathulata a medio infra carnosus et conspicue carinatis intus.

Stamen 1, sanguineum, petalis longioris, primo aspectu, stylum mentiens. Anth. minute terminalis, bilocul.

Stylus brevissimus sanguineus. Stigma terminalis discoidea ovar. rudiment. ad sunt staminodia circa fœm. rudim.

Fœm. Cal. corolla maris, but the coalition of petals with the torus or stalk of the ovary is much more evident. Stam. 2-3 abortive uno multo majore.

Ovar. obovatum apicem paullulum obliquum, stylo subulato petalorum longitudine. Stigma capitat. subreniforme.

Ovulum 1, anatropum appensum foramine fundum loculi spectans.

This is a stately magnificent tree, panicles exceedingly elegant cream colored. Petals white outside, inside except the margin, beautiful lilac.

The male flowers are much more numerous than female, the latter when present are terminal on each cyme. This is a very distinct species, and does away, in some measure with one of the peculiarities of *Syndesmis*, and is at once distinguished by the cohesion of the base of the petals and the elongated torus, as well as by the long erect gamopetalous looking petals.

HAB. Malacca. It has the habit of *Mangifera polycarpa*, Malay name *Beenjai*.

3. *Mangifera polycarpa*, Gr. or russet fruited mango Pl. DLXVII. Fig. II.

Branches stout, confertly leaved at the apex. Buds protected by numerous brownish scales. Leaves, nearly a foot long tapering into a short stout flattened petiole, cuneate obovate undulate, more or less coriaceous, entire, obtuse.

Secondary veins, very distinct, well arched, not confluent, interveniis reticulatis, above dark green, below pale.

A large tree much like the *Beenjai*, both are among the handsome Forest trees, with a fine trunk, massive branches and a flattish thin crown, putting me in mind (from the branches) of *Magnolias*.

The specimen from which this last description is derived was a young tree. The differences in the leaves between this and the Beenjai are in the smaller size more obovate form. I have not seen the flowers of this, or the fruit of Beenjai.

Fructus oblongus basi paullo majora, sublobulata, hinc infra apicem depressus, brunneus, dusky all over, of a strong dorian or mango smell, not altogether unpleasant, with very acid and pleasant taste.

Flesh and juice especially copious, fibres very abundant.

Drupe outline lanceolate, rather compressed, it is not even woody, but coriaceo-fibrous, seed erect.

Integument separating with the drupe, of chesnut brown or black colour.

Embryo erect obclavate radicle on one side above the base.

On one side is a straight furrowed line, on the other an oblique irregular waved one, these are the edges of the cotyledons, which are very unequal, it is the larger one which is produced downwards, so as to make the radicle oblique.

HAB. Malacca.

This I find is the *Camang*, and I propose for it the name of *Mangifera? policarpa*, in allusion to its russet colored fruit, which seems to me unique in this genus.

a. One side of seed.

4. *Mangifera odorata*, Gr.

Arbor magna. Folia ad apices ramulorum sparsa. (Petiolis uncialibus e medio infra incrassatis) oblongo-lanceolata cuspidato-acuminata coriacea, glabra subrepanda, venis 2-dariis distinctis, conspicue arcuatis.

Panicula terminalis, subglabra, fusco-viridescens, præsertim divisiones ultimæquæ cymosæ.

Flores polygami carnei suave odorata alabastra oblongo-conica.

Cal. e sepal. 5, oblong.

Pet. lanceolato-ovata, e medio refracto-reflexa, viridescens

sanguineo-tincta basi cordata, venis infra medium subcristatim elevatis.

Stam. 5, 2 sæpius 1, perfect, arising from a fleshy torus considerably above the plane of insertion of the petals. Filam. subulata sanguinea. Anth. purpureo-lilacinæ versatili biloculares.

Ovar. globosum glabrum. Stylus albus declinatus arcuatis, hinc sulcatus. Stigma simplex.

Ovulum anatropum, ex apice funicul. subbilariter orient. geniculat. flexi transvers.

Fruit like that of the *Bachang*, and with as bad an odour, oblong, filled with sticky gum exuding on being cut, yellowish green with yellow spots and a central disc of a reddish colour, which under a lens presents pores or holes, not compressed, situation of the style obscure, oblique.

Flesh yellow not unpleasantly scented, not turpentinish like that of an ordinary mango, very fibrous sweet, and plentiful, so that culture might make this a good fruit.

Stone very much compressed, covered with torn fibres, rather thick, lined with a parchment-like substance with oblong white markings.

Seed compressed very subreniform, outline with brown cellular coriaceous teguments, internally of a darker brown, much like a huge pear. Embryo of the same shape. Cotyledons flesh-colored, rather rugose with green edges, one as it were, just placed over the other, at the apex, is a little larger, both are equal at the base.

Radicle strongly curved and adpressed just like a curved Leguminose embryo. Plumule stalked conspicuous.

HAB. Malacca. Oct. 1842. Malay name *Koeene*, or *Kohini*. Proxim. *M. indicæ* et *M. foetida*, *bachung*.

SP. CHAR. Fol. petiolis e medio incrassatis oblongo-lanceolatis acuminato-cuspidatis subrepandis coriaceis, venis 2-dariis conspicui arcuatis. Paniculis terminalis pyramidalis, divisionibus cymosis, floribus polygamis. Petal e medio reflexis calyce applicitis, staminibus e toro elevato. Stylo declinato.

Obs. The best marks of distinction are perhaps drawn from the fruit and the seed.

5. *Mangifera foetida* Gr.

Fruit oval, not compressed, apex oblique, green, smooth, with a very foetid smell, that of the common mango with a suffocating, most disagreeable addition.

Flesh yellow, thick, passing gradually into yellow fibres towards the drupe. Drupe covered with white fibres, compressed, almost two-edged, inner layer tough, parchment-like, seed erect, conformable, tegument chartaceous whitish, (brown inside) separating rather with the drupe than the embryo.

Cotyledons equal, oblique at the base, each with an auricle incumbent on the apex of the radicle, one margin (of the two together) as it were, elevated and thickened, so close together as to appear on a transverse section almost united, radicle short, almost a right angle with the cotyledones. Plumula conspicuous.

Fructu ovali, apice obliquusculo e compresso viridi foetido
HAB. Malacca: Malay name *Bachang* July. 1842.

6. *Mangifera longipes* Gr.

Arbor.

Fol. alterna, petioli 2-2½ unciali teres graciles, basi incrassati. Lamina oblongo-lanceolata acuminata subrepanda coriacea glabra, venæ 2-dariæ radiusculæ conspicuæ interveniis minute reticulatis (Sapindacea.)

Panícula terminatis, subpyramidalis tenuis, divisionibus alternis cymosis vel racemosis. Bracteis inconspicuis deciduis.

Flores inconspicui polygami, vel masc. vel fæmin.

Pedicelli calycesque puberuli.

Cal. basi planiusculus e 5 sepalis, lanceolatis patentibus.

Pet. totidem angusti-lanceolat. ad medium subito-reflexa (refracta?) albida, centro basique lutea.

Torus conicus papillosus e quo stamina oriuntur.

Stam. fertile 1, filamento longiusculo subulato glabro.

Anth. versatilis transversa purpurea (sterilia, parva, 2-3,) bilocularis longitud. dehiscent.

The cone is more or less 5-lobed, each opposed to a filament which arises from within its upper margin.

Ovar. subrotund. glabrum e cono $\frac{1}{2}$ exsertum. Stylus obliquus longitud. fere filamento-subulatus glaber. Stigma terminali simplex.

Ovulum oblique ascendens, foramen infero.

Stam. quoad ovarium vero hypogyna. Tendency to carination of the petals at the base.

Petals with 5 elevated striæ or veins to which yellow colour is confined, these confluence below.

HAB. Malacca, Malay vernac name *Boa Pow*.

It appears to approach to Roxb. *Mang. sylvatica*.

Mangifera longipes, petiolis elongatis, fol. oblongo-lanceolatis subrepandis.

Panicle terminali tenui, pedicellis cymosis, racemosis, fasciculatis vel solitariis, petal. tertia medio refractis, basi 5-striatis. Toro 5-lobo inter stam. et petal. Stam. fertile 1. Stylo erecto, ovarioque glabro.

BOUEIA.

Boueia macrophylla, Gr. Pl. DLXVII. Fig. IV.

Arbor mediocris aspectu Guttifero. Corona oblonga densissima.

Ramuli teretes glaucescentes.

Folia opposita, petiola $\frac{1}{2}$ uncialis $\frac{1}{2}$ torta, lamina oblongo-lanceolata obtuse acuminata vel cuspidata crassa coriacea, patentia glabra, venis secundariis crebris sub Guttiferinis arcuatis distinctis interveniis more Terebinth: reticulatis. Gemmis (floralibus) axillaribus et terminalibus ovato-globosis squamis arcte imbricatis.

Paniculæ thyrsoidæ axillares foliis breviores densifloræ, divisiones ultimi cymosæ, ramulisque trichotomis.

Flores polygami parvi inconspicui virides, cito fuescent.

Cal. minutus subpubescens, 4-partit.

Petala erecta connivente imbricata concava, marginibus incurvis spathulato-obovata carnosæ ! centro carinata, inserted by the stout fleshy bases into a torus above the level of the insertion of the calyx.

Stam. totidem interdum 3-5, petalis multo breviora, filam. ima basin connatis, inserted by their stout fleshy bases into a torus above the level of the insertion of the calyx. Anth. biloculi lateraliter dehiscentes, connectivum in mucronulum product. Rudiment. pistila minut. in basi cupulæ filamentor. connectorum.

Flos fæmineus whenever it exists, semper e centro trichotomus, much less numerous than the male. Calyx pubescens, 3-partitus. Petala et Stamina ut in mare.

Ovarium paululum obliqua, pubescens vel glabrum. Stylus robustus subulatus.

Stigma terminali hinc singularia, capitatum subintegerrime as if formed of two reniform lobes. Ovulum 1, suberectum attached to the ventral suture near the base, foramen inferum, tegument duplex, interius inclusum.

In the young fruit, the drupe is little or none, the seed large purplish, oblong reniform with a veined testa? an inferior curved radicle and rather unequal cotyledons. Is there a tegument? if not, the cotyledons are veined outside.

Fruit oblong ovate, little oblique, about the size of a hen's egg, not compressed, it is surrounded at the base by the remains of the perianth.

Pulp yellowish copious with fine fibres of a very acid taste without any admixture of turpentine or the usual mango flavor, although there is a slight mango smell. The nut, if it can be called so, is very thin, leathery, easily

cut, fine fibrous externally, this is lined inside by the adhering brown teguments of the seed.

Hence the embryo appears quite naked on opening, the drupe becoming exposed and conspicuous from its lilac colour.

Cotyledons equal plano-convex, outside reticulate rugose from the pressure of the inner surface of the drupe, inside of a deeper lilac ! Embryo erect. Radicle curved, on line of the commissure of the cotyledons. Plumule conspicuous : a form of Leguminous embryo.

HAB. Malacca. Melay name *Roomanya Bartool*.

This is the large leaved species, which grows to a good sized tree, with a very dense oblong crown.

The smaller species, of which I have a flowering specimen from Rev. Mr. White : is the *B. Peego*, or from its very small leaves, *B. microphylla*. It also attains the size of a moderate tree, and has a dense crown.

The genus is certainly distinct from *Mangifera*, in habit particularly, but scarcely in the flowers, taking *Mangifera* comprehensively (*Langoot*, *M. lagenifera* as the test) and in the scarcely drupaceous evalvular fruit.

In the *Mangifera oppositifolia* of Roxburgh, Wight and Arnot say the style is composed of 3 combined, and that there are 3 stigmas, of which 2 are abortive, and 1 fertile, and much larger.

Now if this were the case, it would be a direct passage to *Buchanania*, and in that group I see nothing like such a structure, and even if the stigma be 3-lobed as Roxburgh says, it does not follow that the style is compound ; on the contrary the ventral suture, and obliquity of the ovarium are against it, besides there is no dorsal sinus ; if stigma, the number of stamina is nothing, the erect embryo nothing, the keeled petals nothing, so that the only distinctions are habit and evalvular nuts, which last are constant.

In this plant there is the commencement of the structure of *Syndesmis*.

2. *Boueia microphylla*, Gr.

Fruit roundish oval, 17-18 lines long, 14-15 in diameter, of a yellow colour, surface veiny mottled elastic fleshy. At the base is a minute subquadrate calyx, and the remains of the style a little below the geometric apex, where also the fruit is rather depressed. Pulp copious, $\frac{1}{2}$ an inch in thickness of rather firm flesh, without fibres as in the mangoes, it is of golden yellow colour and of a rather pleasant subacid taste, tainted with that of turpentine.

Drupe thin, rather tough but not bony, outwardly floccosely fibrous, compressed, 13-14 lines long, 5 across the small diameter.

Seed conformable, the tegument is of the colour of burnt umber, thin, adhering to the inside of the drupe, partly separable.

Cotyledones rather unequal, firmly fleshy, lilac purple especially when cut. Surface irregular and veiny.

Radicle inferior. horizontal, on a line with the lower edge of the cotyledons.

HAB. Malacca. Malay name *Candanghan*. It is a variety of *Roomanya* Baitool, the *Roomanya* Pego, is a bastard kind, not called so from Pegu, as some say.

AMYRIDACEÆ.

SABIA.

Sabie sp. Pl. DLXVIII. Fig. 11.

This plant is supposed to be a *Sabia*, if so, the character does not agree with that of *Amyridæ* in any one essential point.

Cal. 5-sepalus æstivatione imbricata.

Cor. 5-petala hypogyna, æstivation imbricata, sepalis opposita.

Stam. fertilia 5, hypogyna, sepalis opposita ! discreta, filam. clavato-complanata viridia. Anthera terminalis bilocularis introrse, valva revoluta dehiscens.

Pollen læviusculum, 1-plicat.

Ovaria supera 2, connata, præsertim basin versus et ima apices styli, unilocularia bi-ovulata ovulis pendulis foramina ad apicem ! loculi fundum ideo spectante, sursum in stylo subulato gradatim attenuata. Stigma simplex vix conspicue 2 connatis format.

Cupula hypogyna glandulosa, evasculosa, 5-angulata, angulis sepalis alternis ! interspatiis denticulatis ovarii partem inferum cingit.

Frutices scandentes, foliis alternis exstipulatis indivisis, venis secundariis paginæ ad medium conspicue nexis arcuatum, venulis ab his dentibus iterum arcuato nexis, interstitiis articulatis ramulis ultimis subclavatis evanescentibus.

Cymis dichotomis paniculatis, inflorescentia axillaris vel terminalis basi squamis gemmaceis. Bractæ minutissimæ inconspicuæ adpressæ.

Flores virides minuti. Vis aromat. nulla.

1. Alabastrum.
2. Imbrication and alternation.
3. Flower.
4. Same viewed vertically.
5. Same, petals removed as well as most of the stamina.
6. Sepals spread out shewing the glandular cup, and its alternation.
7. Genitalia.
8. Anther laterally.
- 8a. Dorsally.
- 9, 9a, 9b. Anthers in various stages of dehiscence.
10. Pollen in water.
11. Pistillum.
12. Ditto opened through the back of one carpellum.

13. Long section, double of pistillum, shews also the disposition of the vessels.
14. Ovulum. I am not quite certain as to its not having a second coat.

HAB. Pannukka Bootan.

This presents to my mind the maximum of opposition, the three outer series being strictly opposed, and if the angles of the cup be supposed to arise from, or point out the union of the barren stamina, the 4th series will likewise be opposite. But I prefer considering the angles as indicating the situation which the additional stamina would occupy, if developed.

This cup is evascular, and I may here remark that vascularity of organs depends entirely on the degree of development, hence stamina, when barren, to have vessels, must be passed a certain point in their development.

The anthers are curious, they open internally along the furrow separating the loculi, by separation of the edge of the valve from the connective hence no inner valve exists, as in almost all other cases.

Moisture causes the valve to return to its original direction, dryness causes its reflexion. The anther is altogether analogous to a single locellus of a bilocular bilocellate anther. Are we to imagine the total suppression of the inner valves, a tendency to which exists in some Hamamelideæ, or are we to imagine the internal union of the margins of the locelli, as the cause of this curious anomaly.

In the earliest stages in which I have been able to examine it, the formation of the anthers remains the same.

Hence even among typical anthers, two modifications are to be found, bilocular bilocellate anthers, resulting from the development of two leaves, and bilocular unilocellate, resulting from that of a single leaf. A distinction should evidently be drawn between these cases, the latter being

unilocular after dehiscence, the former being in every stage bilocular.

Lastly the ovary offers the anomaly of a vascular fascicle in the same line or nearly so as the placentæ.

The normal condition of an ovary is, to have one vascular fascicle in the axis of its dorsum, this may, or not be ramified in the ovary, but in almost all cases, it is single in the style; when not so, the number of carpella seems to be indicated by the grouping of the fascicles. This occurs in Cucurbitacæ which seem to be binary carpelled, and the fascicles are divided into two groups, this point, however, requires fresh examination.

In this plant the fascicles are 4, and one of these is larger than the others, and it would appear to be generally separable into a fifth. As no fascicle has a right to exist in the situations these do, I conceive them to indicate the abortion of at least two, and perhaps three other carpella; and moreover, as vascularity is a test of perfection, that the apparently two styles, are nearly formed of 2 each, or one of two, and one of three. This must be the case, if my views of the permanence of the test afforded by the number of vascular fascicles in the style as an indication of the real number of carpella, be correct; because the styles, being more permanent than the ovary itself, must be developed considerably to enjoy such a supply of vessels.

The true affinities of this plant are obscure, it is nearer Burseracæ than Amyridææ.

The nearest affinity is probably with Celastrinææ.

Pollen albidum, immers. globos. triplicat.

Ovaria 5, sæpius forsā 6, minuta villosa staminibus paullo breviora.

Styli breves. Stigmata simplicia emarginata. Ovula 2 atropa, erecta, secundo longiusculi prominente ad anthesin etiam.

HAB. Malacca.

Arnott and Wight make Jack's species to belong to *Rourea*, but Jack says nothing of the æstivation of the calyx, and this judging from Arnott's character of *Rourea* is the only distinction between *Rourea* and *Cnestis*: Jack's Plants are *Cnestes* of Endlicher, who makes *Rourea* a synonym of *Connarus*.

Robergia hirsuta, as has been well suggested, is very likely *Phlebochiton extensus*.

This plant seems allied to *Cnestis polyphyllus*. Lam.

EURYCOMA.

Eurycoma longifolia.

Frutex 7-10 pedalis. Ramis sæpius simplicibus apicibus proliferis, foliis summis cujusque crescentiores abortivis et in forma processivæ subulatorum apicibus incurvis ferrugineo-pubescente remanentib.

Caulibus apicibus dense læteque ferrugineo-pubescent.

Fol. sparsis, confectis ad apices ramorum impari-pinnatis, pluri-jugis 2-2½ pedalis, foliolis oblongo-lanceolatis subsessilibus, superne ad basin subobliquis obtusis penninervis, nervis indistinctis juniorib. supra læte viridib. infra argenteo-glaucis senioribus supra atro-viridib.

Petiolis basi incrassatis ferrugineo-pubescent.

Paniculis axillaribus solitariis foliis multe breviorib. ferrugineo glanduloso pubescente.

Floribus minutis solitariis, brunneo-sanguinea, cal 5-sepal. sepalis lanceolatis more pedunculi pubescent. æstivatione valvatis.

Pet. 5 erecto-patentia hypogyna lanceolata sepalis alternantia, breve pubescent. apicibus incurvis æstivatione valvata, more sepal. sed multo minus dorso ferrugineo-pubescent.

Stam. tot quot petala, iis alternantia libera hypogyna filam. subulata, rubro-coccinea ut petala intus albido-pilosa.

Anth. biloculares longit. lateraliterque debiscent. basibus affixæ. Stam. ad basin 2-glandulosa, glandulis oblongis luteis sessilibus, stylus crassus brevis.

Stigma 5, subcapitata lutescentia, carpella 5, extus pilosa, inter se vix cohærentia, ovulum 1 cuique carpello, erectum, foramen conspicuum pilo oppositum.

Eurycoma longifolia Jack.

Mergue In sylvis. Ins. Madamaca apud Peleit: Nov. 1834.

LEGUMINOSÆ.

CROTALARIA.

1. *Crotalaria bracteata*.

Herba 2-3 pedalis, ramosa pubescent. Rami teretes.

Fol. 3-foliolata, petiolata, (petiola superne canaliculato) foliolis lanceolatis subacuminatis cum mucrona, integris, subtus pubescentibus, terminali majore.

Stipulæ deciduæ, subulatæ, parvæ fere rectæ.

Racemi oppositifolii terminalesque.

Flores cernui primo lutei demum aurantiacei.

Pedicelli basi bracteati.

Cal. basi 2-bracteatus. bilabiatus 5-5½ partibus, vexillum cordatum acutum reflexum.

Alæ oblongæ, obtusæ parvæ, carina falcata concreta acuminata.

Stam. monadelpha tubo antica ad basin fissura. Anth. oblongæ.

Ovarium 1-locul. Ovulis 00. Stylus curvatus, antice pilosus. Stigma obliquum subcapitat.

Legumen teres, subinflatum villosa-tomentosum, polyspermum, pedicellatum, pedicello libero.

HAB. In ruderatis, Moulmein : Dec. 1824.

2. *Crotalaria* sp.

Herbacea basi suffruticosa Fol. palmatim 5-foliolatis, foliolis inæqualibus lineari-spathulatis, mucronatis, emarginatis, ciliatis, subtus sericeis.

Racemis terminalibus bracteatis. Bracteis lanceolatis acuminatis deflexis. Pedicellis subnutant. basin versus oppositis 2-bracteolatis.

Calyce $\frac{2}{3}$ bilabiato, dentibus subæqualibus, vexillo alisque luteis, brunneo-striatis carina naviculari viridescente. Leguminibus inflatis, ovulis reniformibus, biseriatis, staminib. 1-delphis tubo superne demum fisso.

HAB. In ruderatis. Pulo Gewen : Nov. 1834.

MELILOTUS.

Meliloti sp. Pl. DLXXVIII. Itinerary Notes, no 1395.

HAB. Assam.

CYTISUS.

Cytisus Laburnum, Pl. DLXXVII. Fig. III.

The legume of *Cytisus Laburnum*, showing the spontaneous separation of the Endorcarp from the Mesocarp along the line of the placental and dorsal sutures. The seeds remaining attached to the two unseparated laminæ : *a* seed, *b* hilum, *c* foramen to which the radicle points : an instance of Mirbels campulitrope seed, May 24th, 1831.

INDIGOFERA.

Indigofera. sp.

Suffruticosa basi caulibus adpressa pilosis, foliis 3-foliatis, lanceolato-ovatis, basi 3-nerviis, lateralibus obliquis.

Racemis paniculatis axillaribus abbrevietis, floribus confertis inconspicuis, vexillum viridescens veniis sanguineis pulchrè notatis, alæ oblongæ purpureæ lateri superiore ad basin limbo dente alba. Carina navicular.

Stigma capitat. exsertum.

Cal. profunde 5-partitus, sepalis lineari-subulatis, antico majora. Legumina ovata, calycis dentem longiorem, subæquante 2-sperma. Cotyledones carnosæ, oblongæ. Plumula conspicua.

Radicula teres brevis curvata. Tubus stamen. superne fissus, ovarium 2-ovulatum.

HAB. In humidis Mergue · Nov. 1834, etiam Moulmein.

AGATI.

Agati grandiflora.

Arbuscula, foliis pinatis, 10-18 jugis, foliolis oblongo-linearibus, obtusis mucronatis.

Racemis axillaribus, paucifloris.

Pedicellis ad basin articulatis, subflora bibracteatis.

Bracteis ovatis foliaceis caducis, floribus maximis, purpureis vel albis.

Cal. infundibulifor. bilabiatus labius utrinque subintegris.

Cor. papilionacea maxima, vexillum ovato-oblongum reflexum longiuscula unguiculat. alæ vexillo longiores falcatae lanceolatae subacutæ. longe unguiculatae. Carina longe unguiculata, navicularis, apice bifida, basin limbum versus 2-dentat. dentibus subrevolutis.

Stam. diadelphe 9 et 1-longissima,

Anth. versatiles. Tubo stamineus basin superne gibbus carnosusque.

Ovarium stipitat. longissime, subcylindraceum.

Stylus filiforme subulatus. Stigma capitat. 1-loculare, multo: ovulat.

HAB. Mergue culta: *Nov.* 1834.

DESMODIUM.

1. *Desmodii* sp.

Herbacea decumbens adpresse pilosa.

Foliis pinnatis 1-jugis cum impari; foliolis oblongo-ellipticis basi subcordatis reticulatis integris subtus glaucis terminali majore, stipulas membranaceas linearib. acuminatiss. stipellis conformibus, minoribus.

Racemis flor. pyramidal. terminalibus, axillaribusque multifloris bracteatis, bracteis ovatis acuminatis, subscariosis nervosis ciliatis, deciduis, floribus binis in axillis bractearum, purpureis, cernuis, pedicellis gracillibus, 2-linealibus.

Cal. tubo brevi, limbo bilabiato partito, lab. super bialato, inferior 3-fido.

Vexillum subobcordat. alis suboppositum intus suturat. purpureo-maculis 2, lutescent, ad unguem, extus pallidum, alæ oblongæ extus saturati purpureæ, intus pallidæ, carinæ subcohærentes. Carina navicularif. utrinque basin versus, 1-dentat.

Stam. diadelphe 9 et 1, tubo stamineo recto.

Stigma capitat. stylus post anthesin in ovario decumbens, Ovarium compressum glanduloso pubescens? 1-loculare pluri ovulat. Legum.

HAB. In graminosis. Mergue: *Oct.* 1834.

2. *Desmodii* sp.

Suffruticosa erecto-ramosa, ramulis pilosis, pilis medio affixis.

Foliis 1-jugis cum impari elliptico-lanceolatis basi cordatis emarginatis cum mucrone, integris reticulatis subtus deflexo-pilosis.

Stipulis membranaceis stipellisque longe acuminatis, subcrescentis Racemis, terminalibus pubescentibus.

Bracteis cordato-acuminatis deciduis ciliatis, floribus binitim aggregatis.

Cal. lab. super emarginato, infer. 3-dentato vexillum carina brevius, carina navicularis hinc medium infra 1-dentat.

Stam. diadelph. 9 et 1, Stigma capitat.

Legumina lomentacea subfalcata, margine superiora placentifera integra venosa, pilis uncinatis hispida articulis, 1-spermi indehiscentibus.

Flores pallide alis saturatius cæruleis notato etiam carinæ apex.

HAB. In hortis prope Mergue: Oct. 1834.

Varias foliolis elongatis lanceolatis angustioribus.

DICERMA.

Dicerma pulchellum.

Fruticosa erecta, ramis verrucosis ramulis velutinis. Fol. pinnatis 1-jugis cum impari, foliolis lanceolatis acuminatis repandis utrinque sed præsertim subtus ad venas pubescentibus reticulatis, stipulis basi latis apicibus setaceis, stipellis basi angustiorib.

Ramulis floriferis axillaribus terminalibusque foliis floralibus distichis imbricatis stipatis. breviter petiolatis, petiola in setam abeunte, 1-jugis foliolis cordato-orbicularib. subrepandis nervosis reticulatis, mucronatis stipulis stipillisque lanceolatis acuminatis castaneis.

Floribus pluribus in axillis folio floralis, coque obteectis, albis cujusque parvis pedicellis brevibus basi bracteolat.

Cal. basi bracteolat. bilabiat, lab. superior integro infer. 3-fido.

Cor. papilionacea, vexillum oblongam sepalis tubo opposit. Alæ lineares late superior ad unguem 1-dentat, lamina breviores carina arcte cohærens.

Stam. diadelphe 9 et 1, stylus pilosus apice glabrus, stigma subcapitat. medio constricta ideoque longe setacea stylo terminal 2-ovulato.

HAB. In sylvis Mergui etiam Moulmein

ERYTHRINA.

Erythrina bisetosa.

Racemis ante flores evolutis, terminalibus secundis densifloris, floribus spiraliter dispositis, maximis coccineis, pedicellis nutantibus, velutinis, calyce extus velutino-pubescent.

Cal. basi 2-bracteolat. bracteolis setaceis deciduis, tubulosus, ore truncato, setas 2 coloratis (dentes) gerenti ad anthesin postice fisso.

Cor. papilionacea vexillo maximo obovato ascendente, postico coccineo carinæque petali conforma, multoties brevior, oblonga obtusissima sanguinea.

Stam. subdiadelph. tubo declinato a medio filamentisque coccineis. Anth. lineares versatiles. Stylus elongatus subulatus. Stigma capitatum.

Ovar. longe stipitatum. fusco-pubescent. velutin. 1-loculare pauci ovulatum.

Circa Mergue, prope luta: *January*, 1835.

MEGALOTROPIS.

Megalotropis buteiformis, Voight.

The following description of the plant in flower, is taken from specimens flourishing in the Bot. Garden Serampore.

4-5 pedalis robusta. Caule parum ramoso flexuoso angulato, pube dense alba.

Stipulis caducis.

Fol. omnino Buteæ subcoriacea subasperula deltiformi-cordata acuminata repanda, subtus albida laterali basi inferne obliqua. Petiolis pedilibus, stipellis fol. laterat. oblique cordato-ovat. solitar. fol. terminalis 2, quasi dimidiata.

Flores racemoso-paniculati, pæniculis erectis, folii subæquant. racemis abbreviatis quasi in capitulos, paucifloros.

Pedicelli sæpe semitorti ideoque flos sæpe resupinatus.

Calyx tubulosus, coriaceis dorso faucem posticum (vexillo opposit) crenat. 3-dentatus non bilabiatus, dentibus 2 posticis confluentibus *emarginatione minima excepta*.

Cor. papilionacea coccinea sericeum vexillum oblongum alas subæquant. alæ oblongis ungue laminam subæquant liberæ.

Carina petalis reliquis longior. condup. convolut. partibus apices versus tantum concretis.

Processus dentiformes coccinei reflexi. utrinque labellum prope apicem unguis indistinctiuscul.

Stam. diadelpa 9 et 1. Filam. infera pilosa. Anth. medio affixæ biloculares longitud. dehiscent.

Stylus subulatus basin excepta glabratus. Stigma oblongo-capitat. terminal.

Ovarium posticum gibbum e basin ad apicem styli gradatim attenuat. Ovula 2 ad formam sursum spectantum.

Legumen junioris, with calyce sphacelate but unchanged, basin stipat. obovate strap-shaped, suturis 2 elevatis (subsessili) so far as regards the calyx the pubescens venoso rugosum.

Semen unicum apicem versus, the lower ovulum now distant and abortive.

Legume in outline scimitar-shaped compressed asperopubescent. suturis præsertim interior placentigeri incrassatis venoso-reticulatis coriaceum apice sublignea. Semen unicum ad apicem teguminum magum, album enclosed in a cell of its own size, the other laminæ otherwise intimately adherent, obovate-reniforme, micropyle mammilate hilum prope.

Tegum. unicum crassim spogiosum, that is, with a spongy *diploæ*.

Embryo conformat semen. Cotyledones superum auriculatæ, auriculis out-topping the apex of the short conical root; which is curved. Plumule majuscula.

I sent the seeds of this plant to Dr. Voight of Serampore, from the Gyntea or Sylhet Hills, alt. 3500 feet, where I found it in fruit in the latter end of the year 1837, it was there a stout suffruticose plant, growing in company; and I called it *Butea suffruticosa*.

PONGAMIA.

1. *Pongamia glandulosa*.

Arborea, fol. pinnatis, 8-jugis cum impari, fol. oblongis basi cordatis, emarginatis, coriaceis venosis. Petiolis supra canaliculat. basi valde tumidis et quasi in cyathum corticis receptis.

Paniculis racemosis amplissimis longissimisque, floribus parvis inconspicuis nutant. calycibus atro-sanguineis, vix sanguineo-coccinea, basi viridescens. alæ carinaque albæ plus minus roseo-tinctæ.

Cal. turbinat. tubo brevi, limbo truncato subinflexo, obsolete 5-dentato.

Cor. papilion. vix cordato-reniformia ascend. alis carinaque brevior. Carinæ petal. ad basin limbi 2-dentat.

Ovar. stylusque brevis pubescens. Stigma simplex, glandulæ ovatæ hypogynæ 10, ovarium basin cingens! parce pilosæ, stylis apicem versus glaber. Ovar. 1-loculare pluri-ovulat.

HAB. Mergui: *January*, 1835.

Ob glandulus perigynus typus Leguminosarum interdum icosand. Affinis sp. 2. *Pongamia atropurpurea*.

2. *Pongamiæ* sp.

Arbor 30 pedalis, umbrosa, foliis pinnatis 4-5 jugis cum impari, foliolis ovali-acuminatis basi inæqualibus, obtusis integerrimis coriaceis reticulat. Paniculis racemosis, terminalibus, fusco-velutinis. Racemis densifloris.

Pedicellis brevibus articulatis basi bracteatis, bractea parva ovata caduca.

Calycibus atterrima purpureis, corolla sanguinea macula lutea ad basin vexilli.

Cal. basi 2-bracteolat. tubo brevi, limbo subbilabiata, lab. super emarginato rotundato, inf. 3-dentato, dentib. acutis, vix ascendens. Alæ oblongæ carinæ longitud. ad apicem unguis, bi-auriculat. Carina navicularis.

Stam. diadelphe 9 et 1, filam. subulata. Anth. ovatæ bilocular. Pollen oblongum hinc sulcat.

Cupula perigyna, obtuse dentata, ovarium pubescens stipitum cingens. Ovula stipulata. Stylus brevis. Stigma simplex acute, 1-loculare, pauci-ovulat. Legume.

HAB. In sylvis. Ins. Madamaca: *January*, 1835.

DALHOUSIEA.

1. *Dalhousiea bracteata*, Gr.

Frutex erectus, ramulorum cortex albescens, stipulæ lanceolatæ, subcoriaceæ, persistentes. Petioli 2-unciales utrinque incrassati ibidemque rugosuli.

Fol. simplicia, ovati-oblonga, basi cordata vel subpeltata, cuspidata, cuspidata brevi-obtusa repanda, subtus parce pilosa utrinque nitida, penninervia, venulæ arcuatæ conspicuæ.

Panícula terminalis pubescens disticha, ramis basi bibracteatis, bracteis stipuliformibus, bracteolæ suborbiculares integri ad basin cujusque pedicelli, et his abortientibus medium versus ramī.

Bracteolæ his omnino conformes sed oblongæ, recta sinistraque, plurivenosæ, alabastra omnino includentes.

Cal. urceolatus quasi depressus, piloso pubescens margine subinvoluta, dentibus 5 obsoletis, quarum 2 anticæ majores.

Cor. papilionacea, vexillum late obcordatum, longiusculi-stipitat. macula lutea unguem versus, alæ oblongæ hinc, denticulatæ. Carina e petalis 2, leviter cohærentibus, bipartita.

Stam. 10 his vexillum versus vel brevioribus, ima basin coalita. Filam. subulata. Anth. adnatæ biloculares.

Ovarium breve stipitatum, 1-loculare sub 4-ovulatum. Stylus subulatus. Stigma terminali subcapitatum papillosum minutum. Ovula, breve funiculata, *alterna*, foramen conspicuum, papilliforme hilum versus styli basi versus aspiciens.

Legumen ovatum, compressiusculum, utrinque acutum subinflatum, bivalve.

Semen 1, an semper, testa ovato-oblongum compressum testa castaneo-lutescente, adhærens. Cotyledones maximæ carnosæ, plano-convexæ semini-conformes. Radicula brevis recta conica. Plumula subconspicua diphylla?

Podalyria bracteata Roxb.

HAB. In Colliculis Chattuc et Charra Poonjee inter : *Oct. 7th*, 1835.

2. *Dalhousiea paucisperma*, Gr. Pl. DCIII. Fig. IV.

Arbuscula, stipulis ovatis membranaceis brunneis deciduis, petiolis utrinque valde incrassatis, foliis late ovatis breviter acuminatis, basin subcordatis integris supra lucidis, venis secundariis arcuata nexis interstitiis reticulatis, floribus axillaribus solitariis.

Pedunculo medio et ad apicem bibracteato, bracteis late ovatis, membranaceis, caducis, bi-articulato.

Legumen breviter crasseque stipitatum, a medio infra brunneum, basi bracteis 2 suffulto, oblongo-ovatum magis ventricosum ac in plantum precedent. subfalcatum, apice acutiusculo compresso, styli ima basi apiculat. nec ne, biloculare bivalve oligosperma.

Semina 1-3 maxima castanea luteo-tincta difformia, faciebus contiguis planis, cæterum utrinque convexis, summo,

infimoque quando triaplaniuscula, lævia, micropyle inconspicue. Chalaza linearis, latiuscula. Raphe inconspicua. Tegumenta sub-3-na extus, intus coriaceo-membranacea 2 interiora præsertim interna cellulosa. Cotyledones semini conformes carnosæ, plano-convexæ. Radicula obtusa fere hæmisphærica hili latus ad superum. Plumula conspicua.

HAB. Assam. Noadwar: *February 17th, 1836.*

CÆSALPINIA.

Cæsalpinia paniculata, Roxb.

Rami teretes aculeis brunneis uncinatis sparsi viridescentes. Folia bipinnata, superiora subpedalia, petiolo aculeato.

Pinnæ distantes, sub-4-jugæ, subdigitates, petiolules aculeolatis.

Foliola 2-3 juga, petiolululi sublineales, lamina lanceolata obtusa coriacea, integerrima, long. 15-16 lin. lat. 7-8 lineali, subtus glauca, et reticulata depresso.

Panícula terminalis, rami inferiores 2-3 ramosi, reliqui simplices, pedunculo communi inferne aculeato.

Flores in pedicelles articulati 3-4 lineali. lutescentibus basi bractea nigrescente squamiformi acuminata suffultes; majusculi aurei.

Cal. tubus obconicus obliquus, nempe centro lateri inferiore contiguo compressus ad bases laciniarum coloratum lineari-oblongarum concavarum reflexo-patentium gibbosus. sepal. infer. (anticum) majus paullo, et cucullatum, æstivatione extinum.

Pet. obovata, sepalorum circiter longitudine, sed duplo latiore, 2 lateralia superiora patentia, 2 lateralia inferiora patente porrecta, 5-tum summum (posticum) minus patens angustior spathulato-lingulatum, æstivatione 2 lateral. superior imbricatum, vel ungue lobo tubo filamentorum imposito lamina cordato-ovata erecta, sanguineo venoso, petalis aliis, duplo minor.

Adelphus villosus-pubescens subdeclinatus, filamentis distinctis insertis calyce ad gibberes, subæqualibus, subulatis, petalis longioribus.

Antheræ brunneæ, lanceolato-ovatæ basin affixæ biloculares, pollen aurantiaceum. Ovarium villosus-pubescens basi angustatum in stylo filiformi viridi staminum longitudini gradatim attenuat.

Ov. centrum placentæ versus 1-ovulatum (an unquam.)

Stylus apice incrassatus, perforatus, aperturæ margines ciliolati, stigma nulla nisi apertura citata.

Arnett makes the colored calyx part of the generic char. of *Pterolobium*.

The leaves were not observed to be ferruginous or rusty underneath, but glaucous.

PARKINSONIA.

Parkinsonia aculeata.

Frutex 10-15 pedalis. Rami flexuosi. Folia bipinnata bijuga, pinnis petiolis alatis complanatis, basibus rotundis incrassatis, apicibus attenuatis. Foliolis parvis, alternis, ovatis petiolatis. Petiolo commune in aculeum desinent. alatus utrinque 1-glanduloso.

Flores racemosi terminali flavi, petalo antico maculis rubris, pedunculatim, pedunculis cum racemo articulatis, flores odorati.

Cal. 5-sepalus, sepalis subæqualibus reflexis lanceolatis basibus in tubum brevem vel potius cyathum persistentem concretis, æstivatio imbricata, sepalo postico reliqua superposito.

Pet. 5 perigyna, sepalis alterna, 4 fere sessilia, 1 antico unguiculato subvexillæformi.

Stam. 10 perigyna. Filamenta biserialia, seriei externa sepalis, interna petalis opposita, filiformia, versus bases pilosa. Antheræ medio dorsi affixæ, bilocul. longitud.

dehiscentes. Pollen oblongum læve in aqua immersum materiam oleosam emittens.

Ovarium sessile. Stylus filiformis, Stigma simplex obliquum, ovar. pilosum, 1-loculare, pauci-ovulatum tegumen basin cyatho persistente stipitatum glabrum.

HAB. Circa Madras frequenter culta, sæpius in sepibus crescit.

CASSIA.

Cassia alata.

Frutex annuus, 4-8 pedalis, foliis pinnatis 12-14 jugis, foliolis oblongis mucronato-acutis, subsessilibus penninerviis, nervis secundariis conspicuis, basi infera obliquis, infimis axillæ proximis, glabris, petiolo supera late canaliculato, stipulis ovatis oblique acuminatis, coriaceis, cito induratis.

Racemis in axillis folior. superior, 1-1½ pedilibus, multifloris floribus, magnis conspicuis, densis, odore subingrato. Pœoniaceo.

Calycis tubo viridis sepalis aureis revolutis.

Pet. flavis.

Stam. 2 maximis fertilibus petalis 2 infimis oppositis, postico intermedio 3-bus, anticis omnino sterilibus, ovarium deorsum curvatum. Stigma truncatum.

Bractea maxima obovato-concava subcucullata cuique flora, tubo calycis stipita.

Ovarium omnino adnat.

Legumina compressa, suture quaque sublignosa, alis 2 maximus transversis foliaceis crenatis, polysperma.

HAB. In ruderalis humidis umbrosisque Mergue in humidis Moulmein : Nov. 1834.

The legumes have exactly the appearance of being formed from two carpellary leaves, the margins of which running outwards from the wings, it is needless to add, that this cannot be the real structure. The leaves according to the Burmese are a specific for psora.

HYMENIA.

Hymenæa courbaril.

Pedicelli crassi in pedunculo articulado, inflorescentia racemoso-cymosa.

Cal. tubo crassissimo ultra medium in sepalis 5, sæpe duorum, vel varia coalitione 3, caducis coriaceis divisus, æstiv. imbricat.

Cor. (no disposition to papilionaceous) ob-petalorum cyathiformis. Petala 5, rotundata sessilia, concava in annulo carnosio, tubo calycis coronata inserta, caduca, pellucido-punctata! æstiv. imbricata, pet. unico intimo sutura dorsali opposito, ideoque vexillum referens.

Stam. 10 annulo inserta supra petala uniseriata.

Filamenta subulata, crassa alba. Anth. versatilis apice subito constrictissima, caduca, æstivat. inflexa et introrsa bilocul. loculis linearibus ad margines, connectivum crassum carnosum reniformum, vasa plura in crescentem disposit.*

Ovarium planum viscosum rubescens, carnosio-coriaceum stipitat. Ovulis plurimis, anatropis, (raphal vessels indistinct, but nearly semi-complete) oblique margo rectus placentiger.!

Stylus filiformis, verrucosulus vel scabrellus, ob. elevationes punct. pellucid.

Stigma reniformia capitat. sinu suture ventral opposit.

A plant with but slight likeness of the family: and remarkable for the fleshy tube of the calyx? and the glandular thick lining, produced above into a thick ring, into which the petals and stamina are inserted as well as for the uniseriate insertions of the stamina, for the articulations of the inflorescence and sepals, for the caducousness of petals and stamens. (Are these last two peculiarities related to each other?)

The stigma is of the usual Leguminous type, which I take

* Æstivat. of corol. and section of the anther, see, α, Pl. DLXXVIII.

to consist of a production of the stigmatic or placental tissue beyond the open end of the convolute leaf, which in this case is united throughout nearly its whole length.

What is the reason why in all this tribe, the stalk of the ovarium is obliquely inserted in the disk and with regard to the axis? In this, the obliquity is towards the ventral suture.

Can the anatropism of the ovula have any thing to do with the rectembriate embryos?

The stigmatic canal is choked up with tissue and surrounded by a ring of vessels, derived from several fasciculi crescently arranged at each suture, the sides of the ovary appear to be cellular, its superficies has crowds of glands at right angles.

Most of the pollen is incomplete, water causes the protrusion of fovilla, which on the application of iodine often appears like an extremely long highly convoluted gut, but not so membranous as those tubes produced in other plants by stigmatic action. It appears to have two coats, both very thin, the outer usually like the inner, with 3-5 pores.

A longit. section of the calyx tube, shews a green superficies with which the sepals are continuous, the rest from which all the genitalia and petals proceed, is white.

The vascular supplies pass up between these two, having previously sent off long branches to the stalk of the ovary; is not this a proof, that the sepals really commence at their articulations? the so called tube being an excavation of the apex of the axis.

The venation presents nothing peculiar, but is far from being as mentioned by authors, faint.

There is a sort of obliquity apparently in the insertion of the leaflets, owing to which, the smaller or oblique margin is innermost, the reverse of the usual position in the family? Were it not for this, it might be considered as the first step towards the formation of a *Bauhinia* leaf, that is, if the leaves of that genus are explainable by the assumption of their being two leaflets, more or less united.

2. *Hymenæa verrucosa*.

Fructus ovoideus, breve stipitatus, stylo basi apiculatus paullo obliquus, suturæ indistinctæ superior distinctior.

BAUHINIA.

1. *Bauhinia* sp.

Arborea, ramuli teretes velutini, sparsim verrucosi. Fol. basi cordata, foliolis ultra medium concretis dimidio-ovalibus, 5-nerv. subcrenat. breviter pubesc. præsertim infra, supra glaucissima, subargentina. Racemis erectis, pedicellis 1-floris.

Cal. bilabiatis rumpens, sepalis reflexis.

Pet. 5, irregul. longe unguiculata, antico majore vexilli-forme plicato-repanda, relique mere repanda.

Stam. fertilia 3, longissima, petalis breviora, deorsum curvata. Anth. lineares versatiles, dorso pilosæ, sterilia 4 filiformia minima, omnia basin 1-delphi.

Ovar. stipitat. stipata inferne calyci adnato. Stylus velutinus. Stigma subcapitat. Legumen 1-loculare stipitata compresso-triangularia.

HAB. In sylvis Moulmein copiosa : Dec. 1833.

2. *Bauhinia isopetala*, Gr.

Frutex, ramis flexuosis pubescent. fol. cordata ad medium fere partit. sinu setigero, 9-nervia, acuta reticulata, integra, coriacea subtus pubescent.

Racemis oppositifoliis terminalibus paucifloris, folior. circiter longitudine.

Pedicellis, ad medium bibracteolatis et ad basin 1-bracteatis. Calyce foliaceo hinc fisso.

Cor. maxime regularis petalo quinto antico.

Pet. ovata 1-nervia.

Stam. 10 fertilia basi 1-delphi, subdeclinat. postica minore.

OXALIS.

Oxalis, Pl. DXL Fig. II.

In the common *Oxalis* of Assam, curious transformations often occur, giving the whole plant, the habit of an *Illecebrum* or *Paronychia*.

Several stages are visible on the same specimen, the first of which consists of a metamorphosis of the sepals into leaves, reduced to one lobe or leaflet.

In this case they originate from the same plane. The petals have a tendency to the same transformation, one being more so than the rest. The stamens and carpellary leaves are nearly unchanged, and these last are opposite the shorter stamina which again are opposed to the leaves.

See Pl. DXL. Fig. II. 1-2-3. In these instances similar shaped leaves are often approximated to those resulting from the mutation of the sepals, so that at first sight the calyx appears double, I should observe that in the calycine leaves, there is often a tendency to *lobation*.

In the next stage the whole or the greater number of petals are similarly changed, the leaves being bilobed. The stamina are diminished in size, but their proportions continue the same. The angles of the ovary are more distinct, and the apices of the carpellary leaves are quite so, they are sterile, their margins distinct not glandular and touching the continuation of the axis which is separate: see 4-5-6.

In the next stage, the stamens are more and more abortive: but still there appears no tendency to transformation. The carpellary leaves have become separated and evidently form a verticillus of leaves attached to a short continuation of the axis, their margins are inflexed, or indeed their limbs are conduplicate, their margins are not ovuliferous. The centre is occupied by a verticillus of conduplicate exunguiculate leaves, alternating with the carpellary ones, covered with stiff white hairs. These appear to me to be the rudiments of a second calyx containing the rudiments of the remaining com-

ponent parts of a flower, but of this I am by no means sure, see 7-8-9.

Another stage presents the great elongation of the axis bearing the carpellary leaves which however have no tendency to explanation, some of the second calycine leaves have become petiolate. Beyond this I can say nothing, these leaves however appear to be more irregularly situated: see fig. 10.

With regard to stage, fig. 6, casual examination leads me to imagine, that the calycine leaves developed at a later period, in the axills of the carpellary ones, are transformed ovula.

The most interesting parts of the above imperfectly examined metamorphosis are, the evidently less tendency in the stamina to assume the form of leaves, the decided objection to explanation in the carpellary leaves, and in their axills becoming the nidus as it were, for the attempt at the formation of another flower.

Naga Hills: *March 10th*, 1836.

2. *Oxalis* sp. Pl. DXL. Fig. III. Itinerary Notes, p. 149, no. 131.

HAB. Bootan.

BALSAMINEÆ.

IMPATIENS.

Impatiens malayensis, Gr. Pl. DLXXVI. Fig. II.

Herbacea, ramosa, caulibus ramisque pubescent. foliis utrinque attenuatis elongato-lanceolatis argute serratis, subtus ad nervos pubescentib. petiolis pluri-glandulosis, floribus axillaribus 4-5 confertis, calcare subulato obtuso, corollam æquante.

Cal. tetra sepalus biseriatis, seriei externa minimi bractæformi, interna sepalo postico emarginato mucronato, infera tubulosa in calcar producta mucronata.

Pet. 2, sepalis coloratis seriei interior alternantia, 3-loba, lobis valde inæqualibus.

Stam. hypogyna 5, filamentis complanatis clavatis connectivis carnosis. Anth. cohærentes bilocular transverse apicibus dehiscentes. Pollen oblongum cellulis areolatum.

Stylus brevissimis. Stigma conicum apice 5-fidum antheris, amplexum.

Ovarium pilosum 5-loculare, loculis polyspermis ovulis pendula e funiculo brevi crasso foramen hilum versus.

Æstivatio calycis imbricato.

Each petal is formed of 2, the upper lateral lobe representing one, as is evident from the venation. *a* lower sepal, *b* upper ditto, *c*, *d*, *e*, and *f* smaller ditto, *g*, *h*, larger petals.

HAB. Mergeue.

Affinis Balsim. coccineæ sed folia non oblongo-ovalia.

Supposing the flower to consist of 9 parts, the arrangement would be thus: 5 sepals, of which the 2 smaller alternate with the upper and outer sepals, 2 larger with the outer and inferior largest sepal.

Hence the 5th which is wanting, would, if present, alternate with the 2 upper sepals, and be opposite the lower or spurred sepal.

The venation of the upper sepal as it really exists, is however opposed to this, as vascular fascicles exists in what appears to be the line of junction of two sepals, whereas it is a general rule, that in such lines of junction no vessels exist; such is the case in the line of junction of the two petals, which appears hitherto to have been unnoticed, but it is a distinct proof of each petal being formed of two, the venation of the upper sepal is similar to that of the lower spurred one, another objection. If we assume the perianth to be quaternarily divided, it becomes strictly normal, but then the stamina and ovaria are quinarily divided. The stigma is covered by a cellular toothed process arising from the base of the anthers.

Antheræ subversatiles dorso paulo infra medium affixæ, biloculares, loculis fere didymis longitudinaliter dehiscentes, deciduæ æstivatione extrorsæ. Connectivum ultra loculos in processum ob-

tusum planum, loculis breviora product. Pollen ovatum læve, hinc sulcat.

Torus discusve hypogynus intra stamina situs, brunneus carnosus, repanda, 5-lobus, lobis conduplicatis sinibus introrsum proficientibus. Rud. ovar. 0. Florum spica trifaria, *i. e.* when unrolled. In the relation of the spike to the axis the angles of the triangle represent the three rows of flowers.

Fam. singula postica.

HAB. Assam. Legi ad ripas fluminis Bheræ: *Sept. 11th*, 1835. Burrumpootur: *April 2d*, 1836.

Obs. In the foregoing description, the leaves are described as sheathing the stem, of this I have great doubts, and if it is the case, a longitudinal section at once shews that the vagina is intimately adherent to the substance of the branch. And yet I think that this, if the joints of the branches be taken into account, is the most rational supposition; a transverse section presents no appreciable difference between the joints and those parts immediately above them. Both are provided with stomata.

The examination of young plants proves, that the leaves are sheathing, and that they are united to the axis, the only difference is in their relative proportion to the points; (which in the young state are not complete,) the proportion between the limb and sheath is reversed in full grown plants, the limb being very small.

SILENACEÆ.

DIANTHUS.

Dianthus nudiflorus, Gr. Pl. DLXXX. Fig. II.

Planta parvula erecta dichotoma vix unquam spithamæa, articulis tumidis.

Fol. basi conata inferior patento-reflexa, superiore ascendente, omnia lineari. sed hæc angustissime.

Flores solitari in axillis et subsessiles, axill. altera ramul. gignent.

Calyx basi induratus textura omnino coriaceus cylindraceus $\frac{2}{3}$ uncialis ratione plantæ longiss. dentibus 5 longis acutissimis, venoso-striatus.

Pet. 5 cum sepalis altern. ungue longissimo longitudine calycis, lamina minima bifida, patens, post anthesin erect. marginibus arcte involutis rubro-carnea, basi pilis paucis erectis, coronæ rudiment. gerent. secus centrum coloris ruber saturator. genitalia inclusa. Habitus quodammodo Pladeræ certe Silenaceus, et forsan Diantho propinque.

HAB. Affghanistan. Barren rocky mountains Otipore: *April*, Itinerary Notes, p. 354, no. 132.

Obs. The relative proportion of the calyx to the corolla etc., during their earlier stages is enormous, the former being nearly perfectly formed when the latter are very minute.

The whorls of the floral series are remote, the corolla and stamen arising from above the base of the calyx, and the ovarium being stipitate.

The stamina and styles are evascular, the petals have 3 veins, all of which are prolonged into the the lamina. Can the two *gibbers* on the base of each lamina from which the hairs arise and which are evidently distinct from each other and

seated on the lateral veins, be referred to two additional series of stamina?

From comparison with one species of *Dianthus*, it is scarcely distinct except in the want of the involucre, which is not universal in *Dianthus*? and the presence of the hairs on the base of each petal.

Arbuscula dioica, ramulis petiolis, pedunculisque ferrugineo-velutinis, foliis ovato-deltoides acuminatis longe petiolatis subtus candidis, venis ferrugineis.

Racemis paniculatis, terminalibus vel in dichotomis ramulorum pendulis.

Fæm. Cal. 3-partit. ovarium papulosum, papulis albidovelutinis demum in corporib. subulatis productis. Stylus breviss. stigmata 3-papillosa, ovarium 3-loculare trifidus loculis 1-ovulatis, ovulis pendulis.

Mas. Inflorescentia paniculato-racemosa.

Sepalis ovatis patentibus extus breviter tomentoso velutinis. Stam. 00 libera hypogyne. Filam. subulata, Anth. ovatæ biloc. long. dehiscent. Rud. fæm central minimum mere spatium nudum.

HAB. In sylvis Mergue frequentur: *Sep.* 1834.

ALEURITES.

Aleurites sp. Pl. DLXXXIV. Fig. III.

Arbor mediocris, fol. alternis exstipulatis longe petiolatis e basi deltiiformi-cordato bi-glandulosis, ovato-acuminatis integris glabris, basi 5-venii, 2 lateral. indistinctis.

Fructus pauce in racemis raminis, in pedunculis ligneis robustis, viridibus pomi magnit. without any conspicuous marks or furrows, etc.

The fruit has certain indications of 4-valvular lines outside.

Substance fleshy disposed to be baccate, bilocularis dispermi seu abortu unispermi. Endocarp. fibroso-coriaceum spongiosum, tela (Testa ?) interjecta inter id. et semen. The vessels are between the fibrous and spongy parts.

Semen erect lateri interior magis planum, subreniforme ossea durissima apice *mammillo*-ossea crassa, lined by a thin cellulo-papery layer.

Albumen copiosum carnosum. Embryo radícula brevis supera. Cotyledon foliaceis planis venosis Plumula conspicua.

Semen habitus Euphorbiaceus.

a Embryo, *b* fibrous coat, *c* cellulo-spongy ditto, *d* drupaceous very hard ditto, *e* like torn paper, *f* albumen, *g* hilum, *h* drupaceous coat, *i* third ditto, *j* chalaza, *l* hilum, *m* raphe, *n* chalaza, *p* mycropyle, *o* drupaceous coat.

Obs. I believe the fibrous coat which easily separates into 2 shells longitudinally, belongs to the fruit, that the seed is pendulous; the spongy coat being testa marked above by a large hilum.

Evidently Euphorbiaceous.

TRAGIA.

Tragia, Roxb.

Monoica scandens, pilis pungentibus hispida, foliis cordato-ovatis acuminatis serratis, stipulis foliaceis cordato-acuminatis.

Racemis oppositifoliis bracteis infimis lanceolatis reliquis linearibus, floribus viridibus inferior fæmineis, superior masculis, fæmineis multo majoribus.

Mas. Perianth. tubo brevi 3-partitum, laciniis latis æstivatione valvatis.

Stam. 3 distincta, laciniis alternantia hypogyna filam tubo longitud. clavata, viridia, in apiculam inflexam, filamenta facie introsa incumbente producta. Anth. bilocul. Connectivum viride.

Fæm. per 3-phylla, sepalis, cordato-ovatis acutis imbricatis ! Ovar. 3-gonum, extus pilis hispida stylus 3-fidus, laciniis viridibus carnosus intus papillos virides (stigmata) gerens, 3-loculare, loculis 1-ovulatis, ovulis pendulis.

HAB. Mergue. Culweng in fruticetis scandens, succo lacteo fætæ.

Genus distinctissima. Per. fæm. 3-sepal, imbricatum maris gamosepal valvatum præcipue nota dignum.

EXCÆCARIA.

Excæcaria, Pl. DLXXXIII.

1. Part of male spike.
2. Male flower, outer view bractea removed.
3. Inner do.
4. Posticous petaliform body.
5. Right lateral do.
6. Left lateral do.
7. 8. Bodies seated on the glands: 7 the right, 8 left.
9. Pollen.
10. Female flower outer view.
11. Do. inner.

12. One of the bodies seated on the lateral glands.
13. Fruit nearly ripe.
14. Ovulum attached, with part of the axis and its cellula cap.
15. Cap detached composed of elongated cells.
16. Section of the testa shewing its opening, the secundine is entire.
17. Section of the secundine.
18. Nucleus.

Excæcaria affinis.

Arbor. 40-50 pedalis, ramulis junioribus viridibus teretibus, Petiolis 2-uncialibus, canaliculatis, rubescent, basibus quasi pruriis, stipulis caducis ex cicatricibus angustatis.

Fol. alterne ovalibus basi subcordatis mucronato-acuminatis, penninervis, nervis secundariis distinctis infimis utrinque ad mediam 1-glandulosis, supra læte viridib. subtus glaucis, floribus racemoso-paniculatis, lutescent.

Paniculis divaricatis terminalibus. Bractea ad basin cujusque floris et utrinque corpus glanduliforme subreniforme areolatum.

Pedicellis pluribus in axillis bractee aggregatis, basi 1-bracteolatis, articulatis.

Perianth cyathiforme irregulariter dentatum. Pet. 0.

Stam. 2 hypogyne ima basin 1-delpha, exserta, filam. crassa longit. perianth cellulosa. Anth. didymæ longit. lateraliterque et utrinque dehiscentes, margo dehiscent, pulchre rubra. Pollen luteum oblongum læve hinc sulcatum.

FÆM. nondum visa.

Affinis Excæriæ.

HAB. Mergue. In sylvis cum *Athroisma dentata*. Nov. 1834.

Flores minutissimi suaviter odorato

Excæcaria agallochum.

Dioicea. Arborea, foliis petiolatis lanceolatis ima basin 2-glandulosis, acuminatis crenato-repandis. Petiolis canaliculatis late marginib. diaphana coriaceis glaberrimis.

Inflores. mascula spicata, spicis axillaribus, solitariis petiolis longioribus odoratis fœmineis etiam spicatis, spicis petiolorum longitud.

Mas. flores solitarii in axillam bracteæ cordatæ reniformi. Bractea utrinque glandulis carnosis viridibus stipata.

Stam. 3, quorum inferius anticum longius monadelpha, tubo staminea brevo. Per. 0. sed cococus. corpora 2 carnosia bipartita, lacinia 1 multo majore, altera, subalata.

Corpora ejusdem generis inter filamentorum quorum superum posticum minus. Filam. subulat. Anth. biloculares, Fœm. bractea ut in masc. Stylus breviss. Stigmato 3, Fructus 3-coccus, coccus 1-pyrenis.

Fœm. Cal. fere ut in mare e corporib. 2 glandulis insidentibus. Cor. vel Per. 3-sepalum, sepalis 2 lateralib. 1-majore, antico supero. Stylus brevis, stigma 3-revoluta, capsula 3-cocca, coccis 2-spermis.

I should observe, that these petaliform bodies vary much in shape, and that the above account as well as the figures agree with that which I have observed to be the most common form.

HAB. In aquosis Mergue : *July*, 1834.

CHAR. GENERUS. Inflorescentia utraque spicata, floribus solitaris in axillis bractearum carnosarum utrinque basin versus glandulis stipatarum.

Mas. Per. 2-sepal. sepalis, lateralibus forma irregulari glandula insidentibus, dextro plurimque basi bi-glanduloso, sinistro 1-glanduloso. Stam. 3, basin versus in tubum concreta. Filam. filiformia. Anth. didymæ connectivo aliquando ultra antheram producto. Corpora 3, petaloidea difformia in sinubus filamentorum, quorum superum (anticum) stamina longiore postico oppositum 3-lobatum, dextrum bilobatum, sinistrum sub integrum. Pollen leve, sulco longitudine.

EPIPRINUS. *Nov. Gen.*

Epiprinus malayanus Gr.

Ramuli (petiolisque) brunnescenti puberuli, teretes robusti.

Folia alterna, conferta. Petiol. 3-uncialis, teretes, utrinque incrassat. lamina ampla e basi cordata ovata, cuspidata acuminata 8-uncial. long., lat. 4-unc., subtus puberula, scabrella basi biglandulosa sub 5-venia, integriusculum, v. secundariæ arcuatim nexæ, v. tertiariis transverse convexæ, inter venulis reticulatis.

Inflorescentia axillaris, racemi paucæ ex axile fol. major. superior, plures ex axillis folior. multo minorve, fere subsessilium.

Racemi vel paniculæ pedunculi robusti carneo-tincti minute puberuli vel furfuracei erecti subdigtales.

Fl. infra medium fæmineis distantes, supra medium (*vel ramulorum*) masculi dense congesti.

Bractea sublanceolata patens vel subreflexa, carnea vel lurida, utrinque basis glandula coccinea subfl. fæmin. quemque 1-bracteolæ 2 minores concolores basin versus pedicelli clavati 2 lineales.

Perianth. biseriatim, exterius e foliolis bracteolis similibus sed longioris magis carneæ erectæ; interius fol. per junior similes lanceolato-acuminatæ, duplo majores, dorso secus centram conspicue costat. griseæ, dorso carneo-tinctæ, interiorum marginibus reflexis.

Stam. etc. 0.

Ovarium parvum subtrilobum triloculare. Ovula solitaria, pendula foramine supero, process. placentæ oblecto.

Stylus robustus basin supra tripartibus, ramis cito palmatim divisus, intus stigmatosa materia badio-papillosa tect.

Ovar. stylusque pilis e basi ob conica fascicul. dense velutinus.

Fl. masculi sordidi rufescenti grisei glomerulati (sub glomerulos bractea carnea acuta, carinata) centrales vel terminales præcociores, sessiles. Per. valvatum cupuliforme, ad medium 4-partitum, lacin. semi ovates.

Stam. 8, filamentis longis, æstiv. a medio inflexis, infra flexura lilacinis vel purpurascente, supra albidis, ad anther.

capillaceis longe exsertis. Antheræ magnæ lutea, cohærentes, oblongæ, basin prope affixæ, pubescenti-pilosæ bilocular. longit. lateral. dehiscentes. Pollen sub ovatum glabum triporosum obscure.

Rudimentum ovarii trilobum.

HAB. Ching, Malacca Nhinghull: *Jan.* 1845.

Obs. This is among my first collection in fruit, but it was not examined; it is surrounded by a foliaceous perianth.

I see nothing approaching to it in Endlicher's Genera, and the characters are so well marked, that it is not a genus likely to have been so imperfectly characterised as not to be recognisable.

BURSERACEÆ.

BOSWELLIA.

1. *Boswelliæ* sp.

Arbor humilis ramulis verticellis plurimis stomatiformibus, petiolis par folioliorum inferiorem subtus, supra planis, foliolis inpari-pinnatis ovatis vel lanceolatis, acuminatis, lateralibus sæpius obliquis. Panicularis terminalibus et axillis foliorum summorum pallide ferrugineis, floribus numerosis albis.

Cal. parvus 5-sepalis.

Cor. rotata basi fere 5-partita, laciniis lanceolatis æstivatione imbricatis. Petala 5, disco hypogyno inserta.

Stam. 10, disci inserta margine exterior. Filam. complanata subulata pilosa, alterna petalis opposita breviora, Anth. erectæ biloculares longit. dehiscentes. Discus glandulosus pilosus ovarium basin ambiens.

Stylus piliformi-crassus. Stigma discoideo-capitat.

Ovarium pilos. $\frac{1}{4}$ inferum basi nempe disco coalit. biloculare, loculis 2-ovulatis, ovulis ascendentibus foramen margine conspicu. Section of the ovary Pl. DLXXXV. A. Fig. II.

HAB. Mergue. Ad littoram Ins. Madamaca vulgatim: *March*, 1835.

It is an exceeding long time between the 1st appearance of the buds and expansion of the flowers, about 4 months. The disk is *not* perigynous.

2. *Boswelliæ* sp.

Arbor foliis pinnatis.

Cal. sepala 5 ima basin fere distincta, ovata.

Cor. 5-pet. petalis unguiculata, hypogyna, sepalis alterna, patentia.

Stam. 10 subdiscum hypogyna ovarium cingens, 10-crenulatum inserta, 5 sepalis, 5 petalis opposita. Filam. subulata. Anth bilocul. longitud. dehiscentes. Stam. 5 sepalis opposita demissius, 5 petalis oppositis superne disco inserta.

Ovarium 3-locul.

Sem. 4-6-8 in quoque loculo, ad apicem in membranam alæformem. Cotyled. crassæ carnosæ punctatæ; radícula brevis superam product.

HAB. Prope Trichinopoly.

CANARIUM.

Canario affine.

Ramulis subteretibus, novellis ferrugineo puberulis. Folia alterna pinnata subpedalia 2-3 juga cum impari. Petiolus subspathamæus. Foliola oblongo ovato petioluto subbilineales cuspidato-acuminata integra long. $4\frac{1}{2}$ $5\frac{1}{2}$ uncial, lat. 2 uncialia.

Paniculæ terminales foliis paullo brevior, pedunculus brunescens angulatis, sulcatus. Flores racemosi vel subcymosi minuti, viridescens, (pedicelli breves vix lineales) extus minute subpuberuli.

Calyx carneo tinctus subobconicus ad medium tripartitus.

Corolla e petalis totidem cordato. rotundatis vel obreniformibus imbricatis, aliquoties majoribus calyptratim secedentibus (an semper?)

Stam. 3 sepalis opposita, paullo sepalis longiora. Filamenta brevissima, basi in anulum carnosum brevem coalita vel inserta; plerumque cum 4to. Connectivum dilatatum subovatum, intus loculiferum, loculi 2, longitud. dehiscentes Rudimentum. Pistilla tridentatum in centro annuli filamentorum.

Fl. Hermaph—?

Fructus basi calyce cinctus pedicell. crassiusculum, clavatum terminans obliquissimum, subreniformis compressum, plumbei coloris et cereus subdiaphanus infra apicem styli base breviter mucronat., basi lateri superiore gibbosus, caro firma, cellulosa tenuis pyrena subossea tenuis.

Semen 1 lateri inferiore prope, stylum affix. conforme.

Tegumentum simplex albidum, tenue. Cotyledones carnosæ, biplicatæ. Radicula supera, (i. e. hilum prope.)

HAB. Malacca Ching. Malacca Nhinghull: Mr. Lewis informs me that in some of the islands of the Indian Archipelago a species of *Canarium* yields all the oil used by the inhabitants. *Jan. 27th*, 1845.

OBS. In one instance I observed a tendency to develop all the parts of the ovarium: i. e. fruit, in æqual-trilobus. This can scarcely be a species of *Canarium*, and it does not come near any other of the characters.

The small number of stamina is not of much consequence, but the shape of the fruit is different.

RHAMNACEÆ.

ZIZYPHUS.

1. *Zizyphus jujuba*.

Arbuscula ramis flexuosis hinc ad basin petiolorum aculeatis, aculeis rectis subdeflexis junioribus breviter pubescentibus.

Fol. petiolatis ovalibus ovatisve serratis obtusis, basi ob-

liquis, 3-nervus, nervis lateralibus extus conspicue penninervus, cæterum obscuris junioribus subtus niveo, senioribus ferrugineo-tomentosis floribus racemoso pallide citrinis.

Racemis axillaribus, abbreviatis multifloris.

Cal. 5-partitus, extus rubescens, laciniis ovatis sinibus calycinis inserti patentibus.

Pet. minora sepalis alternantæ cuneata, subcucullata.

Stam 5 petalis opposita cum iis inserta.

Discus epigynus obsolete 10-lobus.

Stylus crassus brevis, Stigmata 2, Ovarium 2-locul. calyce adnatum, loculis 1-ovulatis, ovulis ascendentibus. Radicula hilum prope.

Æstivatio valvata, serratis plicato-conduplicata.

Culta obfructum, Moalmain Mergue: *October* 1834. Uti omnes plantæ quæ ubiquæ cultæ sunt magnopere variat.

2. *Zyzyphi* sp. Pl. DLXXXV.

Frutex subscandens, cortice brunnea ramulorum novellorum fusco-viridis, spinis brunneis, foliis supra saturata viridibus subtus subglaucescentibus, floribus a petalis viridi-lutescentibus.

HAB. Patakaye mounts Moolumboo Delvi: *March 27th*, 1837.

VENTILAGO.

Ventilago sp.

Fruticosa longe scandens. Fol. alternis bistipulatis, stipulis ovatis membranaceis minimis deciduis, petiolis brevibus rubescent. fol. ovat. oblongove ovatis emarginatis obtusissimis integris glabris reticulatis.

Racemis paniculatis, axill. et terminal.

Calyx fructus discoideus truncatus demum marginibus crassis, fructibus, oblongis foliaceo-alatis, ala quoad cavitate semenifer maxima ovata 1-nerv. rubescent. nervo medio,

marginibusque lutescent. basi 2-locular. loculo 1, sæpe abortient. 1-ovulat. ovulis erectis, foramen hilum prope.

Semina globosa vel si bina hæmisphærica. Embryo minutus in excavationem basilari. Radicula brevis infra hilum spectans. Cotyled. foliaceæ orbiculatæ. Plumula inconspicue, albumen carnosum copiosum. Pl. DLXXXV. Fig. III. *a*, dark coloured vascular lines, *b* albumen, *c* vitellus.

HAB. Mergue. In sylvis collinis Palor: Feb. 1835.

GOUANIA.

Gouania leptostachya.

Scandens, subglabra.

Foliis alternis petiolatis (petiolis canaliculatis) cordato-ovatis, obtuse acuminatis late crenatis, supra atro-viridibus lucidisque, infra pallidis et ad nervos pubescens.

Racemis subpaniculatis longissimis nutantibus pubescent. floribus numerosis, parvis albis, 2-4 fasciculatis in pedunculo brevissimo odoratis, *odore prussico*, in pedicellis brevissimis articulatis.

Cal. tubo brevi, limbo 5-partito, ovario longe adnato persistente? laciniis leviter subpatentibus æstivatione valvatis.

Pet. 5 minima cucullata, sinubus calycinis inserta, stamina obtegentia.

Stam. in annulum 10-dentatum calyci adnatum unita, dentibus 5 petalis oppositis antherif. 5 oppos. sepalis, sterilibus, oblongis emarginatis. Filam subulata brevia, Anth. biloculares subversatiles, loculis longit. dehiscens. Pollen leve. Styli 3 brevia filiformia. Stigmata totidem obtuse pupilloso.

Ovaria infern. nempe tubo calycina adnat 3-loculosa, loculis 1-ovulatis, erectis foramen hilum versus. Long. and transverse section of ovarium &c. Pl. DLXXXV. Fig. II.

Cirhi longissimi ex apice ramularum *pedunculi transformati*. stipulis minimis membranaceis. Discus epigynus

ad faucem calysis in annulum denticulat. stylus subam-
plectens clavatis.

HAB. Mergue. In Sylvis Ins. Madamaca: Oct. 1834.

RHAMNUS.

Rhamni sp. Pl. DLXXXVI.

Frutex scandens, cortex ferruginea, fol. subtus glauces-
cente supra saturati-viridia, l-venia subtus subtiliter punc-
tulata. Ramuli viridescentes. Flores viridescentes fortiter
sed subingrate odorata.

HAB. Patkaye mountains. Vix occurrit infra alt. 3000
pedum.

AURANTIACEÆ.

Obs. In *Ægle marmelos*. *Bel*, the septa have *pellucid* or glan-
dular dots: the funicle arises from an irregular areola,
situated near the inner angle.

In *Murrya exotica* the stamens are not inserted into the
disk.

LIMONIA.

Limonia sp. *nova quoad*. D. C.

Arborea, foliis lanceolatis in petiolum apicem articulatis,
acuminatis obtusis repandis glaberrimis pellucido-punctat.

Floribus viridescens odoratis paniculatis, paniculis
axillaribus folior. circiter longitudinis, dichotomis corymbosis.

Cal. minimus, 4-partitus.

Pet 4 linearia sepalis alternantia apicibus cucullatis, deci-
duis.

Stam. 8 libera biseria seriea externa sepalis opposita
paullo longiora. Filam. petalis paulo breviora subulata
basibus plana ciliataque. Anth bilocul. longit. dehiscentes.

Torus luteus clavatus angulis 10, staminib. oppositis, ad
apicem pilosum.

Ovarium pilosum, stylus brevis filiformis, stigma subcapit. sub 4-lobum, 4-loculare, loculis 2-ovulatis ovulis superascendent. inferiore majora pendulis, foramen hilum prope. Fructu maturescent. torus disapparet loculis amplis factis ovulis minimis. Endocarp. separatum.

Pedicelli paulo infra medium bracteate. Pl. DLXXXVI. Fig. II. section of ovarium with ovules.

HAB. Mergue. Ad littoram. Ins. Madam.: August, 1834.

CITRUS.

Citrus scandens, Gr. Pl. DLXXXVII.

Frutex spinosus scandens. Spinis *ramulinis* vel inflorescentibus et tunc minoribus.

Ramuli petiole, et folia pubescentia.

Flores albi, uti stamina, suave odorata. Petala extus medium supra viridi tincta.

HAB. In sylvis collinis near the Serpentine Mines versus Burmam.

April 3rd, 1837.

Species distinctissima. Ord. Assamia superiore raro occurrens: in vallem Mogoung frequenter, specias quatuor legi versus Serpentine mines.

GLYCOSMIS.

Glycosmis quinquefolia.

Frutex ramis laxis, fol. pinnatis pinnis alternis, (vel 3 foliatis), oblongo-lanceolatis, subacutis, irregulariter subserratis senioribus subintegris pellucido-punctata.

Paniculis cymosis axillaribus terminalibusque foliis brevioribus rubescente velutinis, cymis sub 3-chotomis paucifloris, floribus inconspicuis albis subodoratis.

Cal. 5-sepalis, sepalis ovatis rotundatis minute brunneo-pubescent. æstivatione imbricatis.

Pet. sepalis alterne obovato, punctulata, æstivatione imbricatis.

Stam. 10 libera, subbiseriatis, 5 externa paulula longiore sepalis opposita. Filam. complanata. Anth. ovatæ basibus sagittatis affixis longit. dehiscent. Connectiv. glandulos. glandulaque terminat. Pollen oblongo-ovatum læve hinc sulcatum.

Ovar. stylusque crassiss. filiform. glandulis elevatis punctat. Stigma truncat. subcapitat. 5-sulcat. medioque foveolat. Ovar. toro albido paulo elevat. insidens 5-loculare, loculis 1-ovulat. ovulis pendulis foramen hilum prope.

HAB. Mergue. In sylvis. Kulweng : Dec. 1834.

Character Wightianus bonus.

COOKIA.

Cookiæ sp.

Suffrutex ramulis viridibus, foliis impari-pinnatis, foliolis alternantibus, ovatis terminali magis lanceolato-acuminatis crenato-repandis, pellucido punctatis, floribus paniculatis, inconspicuis viridibus.

Paniculis terminalibus divaricatis.

Cal. 5-sepalis, sepalis minutis.

Petalis 5 caducis glandulosis ovatis suberectis concavis.

Stam. 10 libera, alternatim brevior, brevioribus sepalis oppositis. Filam. sepalis brevior basibus dilatata sub 3-angularia, superne subulata, partis dilatatæ marginibus inter se leviter cohærentia. Anth. basi affixæ bilocul. longit. lateraliterque dehiscentes. Pollen aureum oblongum hinc sulcatum.

Ovarium toro parum clavato-insidens, obsolete 5-lobum, stylus crassus viridis filiformis, stigma capitata obsolete 5-lobum, 5-loculare, loculis 2-ovulatis, ovulis pendulis collateralibus foramen ad apicem conspicuum.

Æstivatio pet. imbricata, 1 exterius, 1 interius. Pl. DLXXXVII. Fig. II. *a* inner-most, *b* outer-most petal, *g* sec-

tion of the ovary and style, *f* portion of placenta with ovules attached shewing them to be collateral, *c* foramen, *d* raphe, *c* chalaya.

HAB. In sylvis. Mergue: Nov. 1834.

BERGERA.

Bergera Kœnigii.

Arbuscula, fol. alternis impari-pinnatis; foliolis oblique lanceolatis acuminatis crenato-serratis, secus nervum medium sub pubescent. Corymbo terminali multifloro, folioloso, floribus albis.

Cal. brevis, 5-partitis basi incrassatus. Pet. totidem, oblonga sepalis alternantia.

Stam. 10 distincta alterno longiora sepalis, alterna breviora petalis opposita, distincta, toro dilatato carnosio inserta. Anth. bilocul. erectæ. Stylus crassus. Stigma capitatum, transverse sulcatum.

Ovar. 2-loculare, apice non ovuliferum sed receptaculum olei utrinque continens. Ovula 1, interdum 2 cuivis loculo, pendula nec peritropa. Tegumenta bina. Pl. DLXXXVI. Fig. III.

HAB. Bengal. Prope Jumalpoore: Sept. 17th, 1835.

OBS. Genus Murrya vix distincta.

Aurantiaceæ sp.

Arbuscula vel frutex ramis laxis, foliis oblongo ovatis, obtuse cuspidatis, integris pellucido-punctatis, axillis foliorum inferior spina recurva (vel pedunculo vel ramo abortivo) gerentibus.

Ramulis petiolis, foliorum nervo medio, infra, foliisque junioribus infra, ferrugineo-paleaceis, foliis alternis obovatis obtusis, subintegris coriaceis irregulariter pellucido-punctatis, floribus axillis aggregatis, pedicellis foliis brevioribus.

Cal. æstivatione imbricata 5-sepalis.

Pet. 5. Stam totidem petalis opposita. Anth. bilocul. cingentia. Stylus brevis. Stigma capitat. Ovar. 5-loculare? loculis 1-ovulatis, ovulis ascendentibus.

Fructibus longe pedicellatis ovatis stipitatis toro nempe elongato, apice parce pilosis, glanduloso-punctatis, baccatis, 1-spermis semen pendula in materia *aquosa* resinosa viscosa indulans. Cotyledones carnosæ. Plumula polyphylla? ulterius examinanda. Pl. DLXXXV. A. Fig. XIV.

Stipite calyce, 5-sepalo stipato (sepalis patentibus rotundatis emarginatis), basi cicatrisata.

Baccæ 1-spermæ 1-locul. vel 3-spermæ 3 locul. an plures? seminibus pendulis. Cotyledonibus carnosiss, plano-convexis, apicibus bifidis! Radiculo supera brevissima. Plumula inconspicua. Pl. DLXXXVII. Fig. III. *a*, radicle, *b* junction of cotyledon, *c* ditto other face, *d* seed externally.

Vidi tantum flores longe ante anthesin, stipulis 0. Habitus *Myrsinearum*.

HAB. Ad littoram Ins. parvæ prope. Pulo Gewen: Nov. 1834.

CEDRELACEÆ.

IXONANTHUS.

Ixonanthus sp. Pl. DLXXXIX. Fig. II.

Semen rarius perfectum pendulum, solitarium, funiculo quasi, maxime irregulariter monstrosus, supra in subulam apicem loculi attingent. product: infra irregulariter lobatum, lobis apicem versus punctulatis subsaccatis, ovula quodammodo mentientibus.

Semen brunnea oblongo-lanceolatum, raphe pallide $\frac{1}{2}$ completa insignit. compressiusculum, chalaza subdepressa.

Albumen carnosum. Embryo thrown out to the external border of the seed.

Cotyledones foliaceæ.

Plumula inconspicua testa coriaceæ, tegumento interius tenuiss. albumen arcte vestiens, tela cellulosa distincta irregulariter interjecta inter tegumenta. *a* attachment of funicle, *b*, *c*, ovule, *d* albumen, *e* testa, *f* embryo, *g* funicle, *h* hilum.

MELIACEÆ.

MELIA.

1. *Melia excelsa*.

Arbor excelsa 50 pedalis, trunco gracili albo altius ramoso.

Fol. ad apices ramorum confert. pinnata 2-2½ pedalia, petiolo tereto, basi versus incrassata, foliol. alterna vel subopposita, oblonga acuminata, basi superne, obliquissima, et subauriculata, repanda, nitida læte virentia glabra, subtus reticulata penninerva.

Paniculis axillaribus, 2-pedalibus, interdum foliolis, compositis subthyrsoideis, floribus in cymis paucifloris dispositis inconspicuis parviusculis albidis. Subodorat. Pedicellis basibus articulatis bracteatisque pedunculisque pubescente velutinus.

Cal. 5-sepalus, sepalis velutinus rotundatis subæqualibus.

Pet. 5, oblongo-linearia patentissima obtuse, pubescent., æstivatione imbricata, 2 exterior, 1-interiora. 1-intermedia.

Tubus stamineus basi dilat. 10-sulcatus, sulcis basi subdisstantibus, membrana interpositis, supra approximatis, ideoque filam 10, basibus dilatata inter se per totam longitudine coalita, apice sub 15-dentat. dentibus petalis oppositis latioribus integrisque, sepalis oppositis, plus minus profunde emarginat.

Anth. subexsertæ oblongæ sessiles bilocular longitud. lateraliter dehiscentes. Pollen globosa læve, aqua immersa papillus 2-3 emittens (Onagracious).

Stylus crassius filiformis media supra papillos. Stigma subconica basi annulat. 3-4 lobum papillosum, annulus carnosus

hypogynus, ovaria basi cingens. Ovar. glab. 3-loculare, loculis 2-ovulatis ovulis pendulis collateral. foram. superum hilum prope. Pl. DLXXXV. Fig. V. single ovules attached to the Placenta.

Gen. discedit. ovaria 3 nec 5 locale.

An *Melia excelsa* Jack, sed caractere DeCandollii erroneus
HAB. Circa Mergue, an culta : Dec. 1834.

2. *Melia azadarachta*.

Arbor. Folia pinnata, dimidiato-ovatæ, acuminata, grosse dentato-serrata, ad apices ramorum conferta.

Inflorescentia axillaris terminalisque, racemoso-paniculata. Flores albi redolentes bracteata, bracteis caducis. Æstiv. corol. imbricat.

Cal. 5-sep. sepalis ovatis.

Cor. 5-pet. petalis lanceolatis sepalis alternis patentibus stamina hypogyna, biserialia, sepalorum numero duplex.

Filam. in tubum coalita. Tubus ad apicem 10-lobus, quorum 1 cuique antheræ respondit, lobis 5 exterior sepalis, 5 interior petalis oppositis. Antheræ ad apicem tubi, longitud. et introrsum dehiscentes.

Stylus 1 tubo stamineo brevior filiformis. Stigma submitræformes. Ovarium 3-locul. loculis 2-ovulat. ovulis pendulis.

Obs. Development. The younger the bud is, the less is the development of the tubus stamineus and style compared with that of the anthers and stigma. In a bud, in which the corolla is double the length of the calyx, the anthers are very large, the lobes of the tube small, not reaching half way up the back of the anthers, while the tube itself scarcely exceeds in length the anther. The stigma is well developed but almost sessile.

HARTIGHSEA.

Hartighsea ramiflora.

Ramuli subsimplices elongati inferne floriferi, superne foliosi, novellæ partes cum fol. nascent. ferrugineo-furfurac.

Folia petiolata 1-1½ pedalia, petiolis angulatus foliola in petiolulis bilineal. supra canaliculatis, alterna, sub ll oblongo-lanceolata, superiore lateri inæqualia obtuse cuspidato-acuminata supra atro-viridia, long. 4½-5 uncial, lat. 1½ uncial.

In the lowest leaves of the axiles, a short raceme sometimes occurs.

Racemi florum ex axillis folior. lapsor. vix ultra unciales, (all at the same state of development) pedunculis infra medium quasi lignosus, squamis brunneis bracteatis notat. parte florifera viridescens ferrugineo-puberula.

Pedicelli sublineales versus medium articulati bractea brunnea squamiformi suffult. Bracteolæ 2 minimæ concolores.

Flores densiusculi 4-meri, majusculi, ochroleuci, cito fuscescentes.

Calyx minimus planiuscula, 4-dentatus.

Petala 4, lineari-oblonga, ad medium tubo staminum erect. et cum leviter adhærent. tunc reflexo-potentia, 4-linealia long. 1½ lat.

Tubus stamineus petalis paullo brevior, pressione subangulatus, subtetragonus, apice dentibus 8 latis brevibus subemarginatis interdum. Antheræ oblongæ, parvæ sessiles in dentium facie interiore, bilocul. longit. dehiscent. Tubus interior triplo brevior crenulatus, crenul. forsan 10, cum antheris altern. ovarium cingens et æquans.

Ovarium brevissime stipitatum subglobosum lepidotum minutissima.

Stylus filiformis vel columnaris, prope basin articulatus longitudine circiter tubo staminei, apicem cyathulo brevi ampliatus. Stigma discoidea subexsertum e cyathulum

supra dictum prominens. Ov. triloculares, ovula bina pendula collateralia, anatropa.

Fructus. ?

HAB. Malacca Nhinghull : *Jan. 27th*, 1845.

OBS. Hartighseæ sp. ? sed foliola non opposita, a tendency to an additional tooth in the staminal column. Column or tube very veiny, the principal axes corresponding with the anthers, along which the tube is also outwardly sulcate, the staminal fascicles appear simple. The inner tube is evascular.

The structure of the apex of the style and stigma render it probable, that this latter texture may be highly exerted.

MONOSOMA.

Monosoma littorata, Gr.

Arbor. Foliis pinnatis 2-jugis, ramis 1-jugis, foliolis obovatis, vel ovato-obovatis obtusissim : coriaceis integris, penninerviis, nervis secundariis suboppositis, subtus pallidior reticulatisque (fol. aliquando abortu solitariis). Petiolulis brevibus crassis brunnescent.

Inflorescente paniculato axillaris. Paniculis pauciflora foliis brevioribus pedunculis pedicellisue clavatis rubescent, floribus inconspicuis viride albidis subsuaviter odoratis.

Cal. 4-sepalus, sepalis orbicularibus minimis.

Cor. 4-petala, petalis sepalis alternantia obovato-oblongis, concavis, patentibus, æstivatione imbricatis.

Stam. 8 monadelpha, hypogyna in tubum apice 8-dentat. (dentibus ovulibus apiculatis) connata. Anth in sinubus dentium sessiles, biloculares introrsæ longit. dehiscent.

Ovarium rotundat. miniatum apice tantum viridescente. Stylo brevi filiformii. Stigma discoideum brevissima conicum, subspiraliter 4-sulcatum. Ov. 4-loculare, basin versus solidum; loculis pauci-ovulatus, ovulis pendulis ab axin central. apicem loculorum versus, foramen inconspic. hilo obversum ideoque loculi fundum versus spectans. Pl. DLXXXVIII. Fig. III. Transverse section of the ovary &c.

Pl. DLXXXV. Fig. VIII. longitudinal ditto.

Fructus maximus, 1-locularis pericarpio crasso leathery, sub 4-valvis. Semina pauca maxima, angulata. Testa crassissima, extus coriacea intus, suberosa. Albumen 0. Cotyledones, maximæ carnosæ, in corpus unicum coalitæ. Radicula subsupera? maxima, testæ cicatrici notat. facilq; germinans.

Ad littoram Insular. et inter Rhizophoreus circa Mergue copiosa. Florens Nov. 1834, fructu, *July, August.*

Habitus floresque Meliacearum, a quibus cotyledonibus cavitatam tantum differt.

CHAR. GEN. Cal. 4-sepalus. Pet. 4 patentia, stam. in tubum monadelphum apice 8-dentatum coalita. Anth. sessiles in sinibus dentium. Ovarium 4-loculare, loculis pauci ovulatis, ovulis pendulis, stylus 1, stigma peltatum subspiraliter 4-sulcatum. Fructus maximus, 4-valvis, 1-locularis. Semina plura maxima angulata, cotyledones coalitæ.

GUAREA.

1. *Guarea oblongifolia*.

Arbor humilis, fol. 2-jugis, petiolis basin petiolulisque incrassatis rubescent. foliolis oblongis obtusis, basi obliquis plus minus, subtus reticulatis.

Paniculis axillarib. foliis multo breviorib. Floribus inconspicuis albis.

Monos. littoratae affinis.

Ad littoram Ins. Madamaca: *Feb.* 1835.

2. *Guarea disyphonia*, Gr.

Arbor 30 pedalis, fol. pinnatis 2, 3 jugis, foliolis sæpius oppositis oblongis lanceolatisve oblongis subrepandis, atros virid. venis secundariis distinctis obtusis petiolis verrucosis basi dilatatis.

Paniculis axillaribus compositis longissimis $1\frac{1}{2}$ pedalibus

pendulis. Pedicillis articulatis brevibus basi bracteatis, floribus majusculis albis.

Cal. 4-dentata, dentibus acutis.

Cor. 4-petala, pet. lineari-oblonga, medium infra conniventia, corollamque gamopet. simulam, med. supra reflexam distinctaque, æstivatione valata.

Tubus stamineus petalis paulo brevior, extus pubescens apice sub. 8-dentata denticulataque. Anth 8 sessilis intra tubam paulo infra apicem bilocular. longit. dehiscent. dentibus tubo oppositis. Pollen subglobosum læve.

Columna hypogyna carnosa, stamino tubo duplo brevior 8-dentato, dentibus sepalis alternant. longe pilosis ovarium intus pilosissima omnino obtegit

Stylus filiformis. Stigma, discoid. 2 annulat. annulo interior minore albo, 4-sulcato.

Ovar. pilosum 4-loculare, loculis 2-ovulatis ovulis ascendent, superpositis foram superia. Pl. DLXXXV. A. Fig. I. *a* annulus exter, *b* ovula in situ with a portion of placenta.

HAB. In sylvis. Ins. Madamaca prope Palor : Dec. 1834.

An Guarea sed character generis magnopere deficiens : ob tubos duos, quorum interius sterili. Disyphonia nominanda.

3. *Guareæ* sp. Pl. DLXXXVIII. Fig. II.

Fructus pomi magnitud. stipitatus, stipite crass. $\frac{1}{4}$ unciali ; lutescens, apice cruciate, lineatus, interstitiis medio longitudinaliter obsolete *foveolatis*. Endocarpio spongioso crasso 4-locularis, 4-spermus. Semina unica in quoque loculo longitudinaliter affixa, arillo maximo carnoso, semen ? fere omnino includent. crasso albo.

Semen ? tegumento membranaceo tenui continent. mass. subrotundam carnosam albid. radícula cotyledonibus plumula conspicuis,

Hæc massa secus lineam medio lineato est sed obscure, sed cotyledones mutuo adherent et centrum versus conum an radícula an plumula continent et cumeo adhærent.

AGLAIA.

1. *Aglaiia sexipetala*, Gr.

Ramuli brunnescentes, teretes flexuosuli. Folia trifoliata. Petiolus teres utrinque incrassatus sub-biuncialis, foliola sub-elliptica breviter et obtuse cuspidata subcarnosa $3\frac{3}{4}$ unc. longit. latit. biuncial : ven. secundariis conspicuis et arcuatim nexis, reticulatis etiam subtus obscure : petiolule fere 4-lineales supra sulcatam.

Panicula ex axillam folii evoluta ultima vix ultra digitum longit. cum partibus nov. minute ferruginea, pilis sublente stellatis, ramis patentissimis brevibus, ultimis racemiforme vel subcymos.

Flores minuti numerosissimi clausi lutei.

Cal. eodem more pubescens 5-sepalus, minimus.

Petala 6, oblonga, concava connivente in corollam apicem depressa parvia, biseriata, seria intima duplo fere minora.

Urceolus stamin. inclusum, apice 10-dentat. dentibus 5 alternis antherifer, 5 aliis obtusis, obsoletis. Antheræ ovato-cordatæ sessiles bilocul. deorsum spectantes, introrsæ. Pollen albidum.

Ovarium stigma magno disciforme capitat. obsolete trilobum coronat. fundum urceoli nuncupans, pilosum vel lepidotum, cylindraceum, minimum.

Ovulum anatropum, pendulum, vel subappensum, sæpe ut videtur nullum, foramen superum.

The observation of the ovulum is difficult, owing to the minuteness of the parts, but certainly it appears single and solitary.

HAB. Malacca at Ching: Jan. 27th, 1845.

2. *Aglaiia Dookkoo*, Gr.

Arbor mediocris, fol. pinnatis petiolis, petiolulis basi incrassatis, fol. alterna oblongis, interdum oblongo-obovat. lateri

inferiorum inæqualiter, subundulat. coriaceis glabris venis 2-dariis obliquum arcuatis, intervenia reticulatis.

Racemis abbreviatis 2-3 uncialibus fasciculatis ex axillis, vetustis, fol. orbatis robustis.

Bractea min. sub floremqueve. Fl. breviter pedicel. pedicello robusto, alabastris cum pedicellis depresso-turbinat.

Calyx minutus 5-sepalus, sepalis basin carnosiusculis.

Cor. connivent. urceolata, petalis 5, rotundatis concavis, apice depresso hiantes, stamina apicis et stigma exponent imbricata, 2 exteriorum, 2 intermedium, $\frac{1}{2}$ intern. (one border overlapped) carnosiuscula.

Columna stamina brevissime depressa et quasi incurvata carnosa, simplex. Anth. 10 intra os inserti, infra antheras tubus angustatur.

Ovar. oblongo-conica. Stylus 0. Stigma a large truncate subpentagonal body, infra medium 5-loculare, loculis 1-ovulat. ovulis pendulis anatropus.

HAB. Malacca at Malim.

This is distinct from the Lanseh of the Malays, than which it is considered much finer, in the shorter spikes, and the broad depressed flowers.

It appears to me closely allied to *Aglaiæ*.

The spikes of the Lanseh are proliferous at the apex. The inner locelli of the anthers are the largest, the outer are, I think, the largest in the Dookkoo.

3. *Aglaiæ* sp.? Pl. DLXXXIX. Fig. 1. *Burseraceæ*. Itinerary Notes, p. 176, no. 898.

Arbor parva : ramulis partibusque novellis, alabastris dense furfuraceosque armatis.

Stipulis caducis linearibus pedicellis excedent.

Fol. alterna brevi-petiolata ovata, vel oblonga, vel obovato-lanceolata obtuse et mediocriter cuspidata integra, subtus ad venas et parce per paginam totam squamis peltatis ciliatis.

Floribus solitariis in axillis foliorum lapsorum deorsum deflexa ideoque (secundi *ramos*.)

Pedicelli petiolis paullo brevior angulata e bracteati.

Alabastra initio involucri omnino tecta. Involuc. valvatum diphyllum : dentus persistentes, per anthesin basi reflexa patens.

Cal. inito tubum oblongum conicum efformans apice 4-valvis, valvis demum per totam longitudine secedent. reflexo-revolutis intus pubescent.

Pet. plura sæpulis ut videtur tria, interdum 4, in sinibus cujusque sepala, lineari-spathulata angustissima, si 3, lateralia minora, vena centrali prædita, et quasi pellucido-glandulosa, æstiv. erecta.

Stam. 00, extima breviora castrata, intima majora completa subnovem seriebus intermed. grad. evolutionis completum cæstendentibus. Filam. ima basin subcoalita subulata, 1-venia.

Connectivum peltatum affixum, vasis tot quot pyxidulis evasi centrali radiant.

Anth. e pyxidis 1-7, sæpius incompletis intimis 4-5-7, erectis e connectivo peltata, omnino discretis, apice poro centrali dehiscent. dente et minuto pubescent.

Pollen globosum, 3-4, plicatum ? The outer coat on immersion appears to contract between the spaces or lines along

which the inner coat is exposed, and this without any increase of size.

Ovarium sessile oblongum, squamis longe pedicilat. pel. tatis pulchre fimbriatis omnino tect. 3-loculare, loculis 3-4 ovulatis; ovula si 4, per paria subcollat. si 3, par inferum impar superum ascendentia, anatropa. Stylus longitudine staminum intimorum perfectiorum, sub 3-sulcatus, stigma terminal. obscure 3-sulcatum.

Branch flowering, nat. size.

1. Flower-bud just opening.

2. Flower-bud opened forcibly.

3. Flower, seen posteriorly.

4. In front, the genitalia removed to shew the petals and their common situation.

5a. Central petal.

6 6, 6, 6, 6. Various outermost effete stamens.

6a, a 1-Pyxidate stamen.

6b, a 2-ditto.

6c, a 4-ditto. 6c, also back view of the same.

6d, a 5-ditto.

6e, a 6-ditto. bifurcate.

6f, an 8-ditto. also composite shews the furrow and disposition of the pyxidæ.

6g, a 6 ditto. under pressure shewing its vascular fascicles.

7. Section, long of anther.

7a. Cells of endothecum.

8. Pollen in water.

9. Ditto acted on by water.

10. Pistillum.

11. one of the scales.

12. Transverse section of ovary.

13. Longitud. ditto, ditto.

14. Ovule.

15. Ovula of one placentæ in situ.

16. Long section of ovule, anatropous with two tegments and a $\frac{1}{2}$ complete raphe.

The fruit, like the flowers, seems to be rare at this season (October) at least; it is ob-obovate clavate, surrounded at the base by the withered calyx corolla and stamens, and is densely armed with conico-subulate, acute thorns.

I have only seen small ones, the largest judging from fragments would seem to be at least as large as a hen's egg.

Trilocular, *by abortion of 1 cell*, sometimes empty. Cells 1-seeded! Seeds oblong, cylindrical or flattened a little on the inner face, erecto-appense attached by a largish longitudinal hilum to near the base of the cell, at this place the abortive ovule will be found. *Arillus* vascular very incomplete; margin irregular.

Raphe etc indistinct. The *young albumen* is so plentiful as to make me think that some will be found in the seed.

Cotyledons foliaceous, (radicle inferior) broad diameter parallel to the axis of the fruit.

HAB. Malacca. In sylvis densis viæ Ayer Punnus et Rhim; also here and there in the forests about Ching.

CHAR. Flores ochroleuco-albidi, aspectu elegantes, specimen desiccata cano albida, vivent. foliis supra atro-viridibus.

Antheræ si plura pyxidibus quam sex, e duobus stamin. coalitis conflata. testatur filament interdum apice bifurcum: the increased size of the filament, and its venation.

Obs. It may appear paradoxical to associate with Bombacæ, a plant which has a plurality of petals, not even being always multiples of the calyx, discrete stamina, and stamens either sterile, or with from 1 to 8-pygidial anther-cells, each opening by a pore at the apex.

But great as the dissimilarities appear to be, they cease to exist upon examination.

In the last edition (2nd) of Lindley's Introd. to Nat. Orders Bombacæ are included in Sterculiaceæ, one of which distinctions is 2-celled anthers, and in the enumeration of the more prominent marks of the tube.

Bombacæ are said to have a calyx with a ruptile dehiscence.

The first statement is an obvious error, the second will exclude *Durio* from the family.

There is however an objection presented by the venation of the filament which may be of some weight. I allude to its having only a single vascular fascicle when presenting no traces of composition, such as furrow, or division. This having two fascicles, when it does present such, I consider it to intimate that the union has been secondary, each fascicle representing that of one phalanx.

The fact of the coalition of the stamens taking place at all, leads me to doubt whether, whenever there is more than one pyxide, the anther is not composite. For the radiation of the vessel towards the pyxid is contrary to the usual venation of anthers, and it would be consonant with the structure of the family both as regards unilocularity of the anther, and composition of certain of these.

There is nothing it appears to me in the petals, when more than one in number, beyond the diminished size of the lateral ones, to indicate, that the plurality arises from excessive and complete division of one lamina, but even this structure may be considered reducible to that of the family, the petals of which have many basilar veins, or several primary vascular fascicles.

The composition of the interior stamina is further pointed out by the corresponding increase in size, as we proceed towards the centre.

From some appearances of part of the pollen when the case is freed entirely from its contents, it is not improbable that its development is gradual, as has been observed by Mr. Brown in certain Aroideæ, with not I believe, a very dissimilar dehiscence of the anthers.

It is to be remembered too, that the radiation of the vessels in the connective is scarcely discernible in old specimens, at least so I find it in macerated specimens.

That the petals are subjected to a process, the opposite of that which affects the stamens is probable, from the lateral ones being occasionally lobed, and from each series presenting that gradual diminution of the size of the veins from the centre towards each side, that characterises the petals of Malvaceæ and Cucurbitaceæ. The lateral ones also occasionally present oblique venation or such as 2 veins which is to a considerable degree incompatible with independent simple organs, and certainly would be in this case anomalous; for all the petals being single and independent, should have similarly organised vascular supplies, this also becomes probable from their situation, for independent petals could not be so disposed without a greater anomaly than the complete division of ordinarily entire bodies.

It appears to me not improbable, that this plant will lend some confirmation to the separation of Bombacinæ from Malvaceæ: the composition or enlargement of the stamens towards the centre being remarkable, and the reverse of what might *a priori* be expected.

It will also turn out, perhaps, that the genera with fractuose anthers have highly compound ones, and such a form is very likely to arise from the cohesion of a number of pyxidate anthers.

Malacca, 1842.

DURIO.

1. *Durio zibethinus*, Pl. DXCVI.

Involucro diphylo æstiv. valvato, foliol. concavis, coriaceis e basi subdeflexa: ascendencia erecta.

Cal. basi insigniter depressus intus in annulam ampliat: tubo magno, breviusculo rotundato 6-gono: his sepalis dorsorum ($\frac{1}{3}$ down,) 5-partit. laciniis erectis, apicibus patentibus, *æstivat. valvata*.

Cor. magna e petalis 5, late obovatis, convolute, when freed from the calyx, spreading, but still concave. Pet. un-

guiculate, ungue crasso extrorsum, concavo. Phalangis tot quot pet. his opposita, eodem modo extrorsum concava, 8-10 filamentosa, filam lateral minoribus et breviorib. versus centrum gradatim ampliatis.

Anth. externæ 3-lobæ, lobis subreniform basi lata confluentibus et filamento peltatæ affixa, loculis very shallow occupying convex edge of the lobes.

Connectivum papillosum, if of 3 stamina, there is only 1 vasc. fasc. to the filament which is radiately lobed above, connective if of more, the central ones which consist of as many as 9, have 3 vasc. fasc. to the filament and 3 empty alternate spaces, but these lacunæ have no such arrangement in the unguis of the phalanx.

There, the outer ones are generally opposite the outer vasc. fasc., the others being few, or none in definite order.

Gradation of vessels of phalanx 1-2-3-2½-2-1.

Each sepal has at its base, and its inflexed portion, a large yellow secreting surface, occupying the whole of that part of the surface.

There is great conformity between a transverse section of the claw of the patal and the base of the phalanx, and in the former the central vein is obsolete, whence an argument in favour of the composition of the Petals.

Stam. 5-adelpha, in torum conoidem inserta, phalanx petal opposita 9.

Pollen globosum paris 3-5? or plica 1?

Ovar. sessile in apicem tori; conoidem oblong. 5-loculare, extus squamis peltatis breve pedicellatis, his pedicellis in fruct. amplexicantur et murices fiunt, peltis deciduis, loculis 5, ovula plura 5-7 sub biseriatim ascendunt, anatropa, foram. hilum prope in latus extern. ovul. Stylus crassus subcylind. pubescens, longit. phalangium. Stigma capit. luteum obsoletus 5-sulcat.

Lacunæ mucilag. in stylum et ovarium.

Involuc. with no external marks of composite alabast. Calyx elliptica apice valvata 5-sulcata, anthophore now very short.

Petals convolute unguis distant.

Its close affinity with *Heteropyxis* is now manifest, the points of difference are the tubular calyx, the undivided petals all the filaments antheriferous, and 5-phalageal anthers with a marginal cell dehiscing longitudinally, and 5-celled ovary.

The direction of development is precisely the same as indicated by the smallest lateral anthers of each phalanx, and the largest and longest towards the centre, and the concavity of the base of the phalanx shews that the former are external as regards the axis, the latter, internal.

In both, the filaments only have 1 vasc. fasc. up to a certain amount of composition, they then have two or three.

The larger stature of the inner stamens which certainly is opposed to what might be expected, is characteristic also of *Malvaceæ*, but none of the plants of that family have such a tendency to composition of stamens, and it becomes worthy of enquiry whether the tubus staminifer of *Malvaceæ* is due to cohesion of the filaments below, or whether it is the basis from which they spring.

Koenig's description and figure are not altogether correct, though he gives materials for a more correct, generic definition than has found its way into DeCand.'s *Prodromus*, the differences which affect the degree of solution of the involucl, the base of the calyx, its distance from the insertion of the involucra, the size of the filaments and style, and their degree of stiffness, may originate from the extensive cultivation to which this species has been subjected.

Koenig has not understood the structure of the anthers, these he describes as mesenteriform.

DeCand.'s definition contains two remarkable errors, one the calyx is naked, the other, petals smaller than the calyx.

A transverse section shews the nectaria to consist of horizontally attached bed of papillæ.

HAB. Singapore. It is the Dorian of the Straits the odor is that of new milk. *Malacca*: 1842.

2. Mature carpella.
3. Ditto part of.
4. Mature seed.
5. Transverse section of fruit.
6. Ditto of seed.

7. Longitudinal section of seed before it has been placed in the ground; embryo much too distinct.

8. Seed after having been planted.

8a. 9, Embryo of ditto detached.

Obs. It is remarkable, that a short time after the fall of the corolla, the foramen or what seems very like it is opposite the hilum, the ovule presenting here a decided aperture, the margins of which are truncated, while projecting beyond this is a remarkably fine membrane, which I consider to be primine, and external, although it is difficult to prove this at this stage of its development. Examined at a later stage the ovule will be found to be curved on its own axis, the integument at this period appears to adhere to the body of the nucleus in small nipple-shaped processes which appear to indicate the normal number of ovula to be three.

It is most remarkable that in apparently perfectly developed seeds, during the dry state, I have not been able to trace any vestige of embryo. The albumen presents a slight difference in its tissue along the middle line; but this is scarcely appreciable. The annexed drawings of the embryo were made from 2 seeds that had been placed in the ground some time.

Can there be some plants which may be truly called *Cryptembryoneæ*?

The testa is considerably vascular, the cords running along the angles or eminences, they are chiefly composed of ducts which however are unrollable.

There is a curious but rather strong resemblance between the outside of the testa and the cotyledons, as will be seen by looking at the sketches.

Quoad affinitas, habitu *Cardiospermeo* (*Sapindacearum*) accedit, structura fructus et embryonis *Hireæ* (*Malpighiacearum*) cujus familiæ exemplo unico *Stigmatophyllo* aristato habitu etiam affinis est. Vidi Bot. Reg. t. 1659. Roxb. Hort. Beng. p. 34, sub nomine *Banisteriæ auriculatæ*

2. *Cardiospermum Halicacabum*.

Flower of very irregular structure, and rendered still more difficult by dislocation.

Sepals 4, in reality 5, the two lowest combined into one, as is evident by the rudimentary central veins when compared with its opposite single one; these are anterior and posterior, the two outside ones are very small.

Petals 4, that which would be opposite to the compound Sepal being wanting, the others are normally situated, each being provided with a scale on the inside, two of which have a greater tendency to pass into stamens than the rest.

Fertile stamens 8, disposed nearly in two phalanges, of these 5 are opposed to the sepals, three are opposed to the compound one, two belonging to it, the middle one to the petal wanting. The remaining two are opposed to the lowest petals, or those between the compound sepal and the lateral ones. The two remaining to complete the series will be found in the shape of two minute teeth opposed to the two remaining petals.

Carpellary leaves three opposed to the wanting petal, and those two which have no fertile stamina.

Alternation and situation of parts. Pl. DXCIX. Fig. III.
d, Abortive Stamens.

c, Sepal.

b, Petal with its scale.

a, Compound.

A system of compensation is visible. The stamen opposed to the wanting petal is most developed; the two petals whose scales have the most antheriform tendency have none but tooth-like stamina. And if the situation (given) of the carpella be correct, we have them developed opposite those parts which are most deficient.

Little is known of the nature of these and other scales, if they represent a series of stamina, then the outermost series

is obviously wanting. In this case the number of stamina will be 20.

Again if the carpella invariably alternate with the inner row of stamina, another series is wanting, which like the outer, would be opposed to the sepals, and will be 25.

1. Sepals.

2. Petals.

3. Stamina—wanting.

4. Stamina—Scales.

5. Stamina—developed

6. Stamina—3, developed, 2 sterile.

7. Stamina—wanting.

8. Carpella—3 developed.

A tendency or relation of analogy is presented to a Polyganous formation.

Sem. rotundiſ penduliſ. Radicula hilum prope. Cotyledonib. more heliciſ tortæ albumeno.

HAB. Mergue. In littoribuſ arenoliſ: *Oct.* 1834.

SAPINDUS.

Sapindus rubiginoſuſ.

Arbor ramuliſ petioliſ pedunculique ferrugineo-pubeſcent. fol. alterniſ pinnatiſ 6-jugiſ (foliis terminaliſ 1 interdum abortient.) folioliſ oblongiſ acuminatiſ repandiſ penninerviſiſ utrinque pubeſcent. impunctatiſ petioluliſ ferrugineo-pubeſcent.

Paniculis terminalibus sub racemosis, ramis divaricatis floribus parvis, inconspicuis suaviter odoratis.

Cal. 5-sepal. sepalis rotundatis valde inæqualib. 2 exterior minoribus.

Pet. 4 hypogyna breviter unico unguiculata sepalis alternantia obovata concave basin versus ciliata laminata, lamina intus medium versus densissima barbat. medium supra constricta.

Stam. 8, hypogyna hinc dejecta filam. sublati villosissimum.

Anth. bilocular, longit. lateraliterque dehiscent.

Pollen obsolete triangulare.

Ovarium superum forme corporis centralis pilosi tunque rudinem. Petalum inter sepala 2 inferior si 2 exteriore (uti videntur) recte sinistraque sunt abortiens.

Torus superne vel postice in glandulos alba sub lobata product. Ovarium extus sericeo-pubescent, profunde 3-lobum. Stylus filiformis inclusus apice 3-fidus. Stigmata 3, acuta 3-loculare loculis oblique ascendentibus, 1-ovulatis, ovulis ascendentibus foramen hilum prope fundum locul. versus spectans.

HAB. Mergue. Ancutta: Nov. 1834.

OBS. The two smaller sepals in the bud are anticus and posticus, the petal corresponding to the two right sepals is wanting. The shorter stamens, are anticusly situated, the whole of them with the ovary or its rudiment is pushed down by the development of the torus posticusly, the hairs of the lamina of the petals and of the stamens resemble closely some forms of dotted ducts. The pores, or adhering granules are very minute and require a high power to define them clearly. The ciliæ of the petals are similarly formed, but the pores are less highly developed. According to Cambessedes the anticus petal is wanting.

NEPHELIUM.

TERNSTRÆMIACEÆ.

General Remarks on the Tea Plant.

The aspect of the specimens of the Tea-growing plant of China in my collection, is so different from that of the Assam plant, that I was naturally led to enquire, (so far as my means would go,) whether the Assam plant is identical with that of China or not.

With the view of determining this point I have examined a large collection of the Assam plant, made by Mr. Masters, a tolerably complete series of flowering specimens of the China plants cultivated in Assam, from the same gentleman, specimens of the Tea plant cultivated in Chusan which are only in bud, and lastly the living plant as it exists in the garden of the estate of Pringitt near Malacca.

The following are the principal differences of each of the above :—

Assam plant.—Stature large, parts distant, leaves very large, very acuminate or cuspidately acuminate, occasionally acute, in the dried state blackish, and not of a leathery appearance. Leaves of the calyx smooth, except the margins which are ciliate pubescent, veins of the petals complete, ovary quite smooth or slightly pubescent. Branches of the style dilated at the apex. Radicle of the embryo small, and plumule large.

China plant cultivated in Assam.—Stature smaller and much more contracted. Leaves much smaller, obtusely acuminate, and of pale leathery appearance, leaves of the calyx ciliate pubescent, ovary densely silky-pubescent.

The Chusan plant, is very dwarf and contracted, leaves small, obtuse or obtusely acuminate, blackish and not of a leathery appearance, leaves of the calyx ciliate pubescent. Ovary densely silky-pubescent.

The living plants at Pringitt.—Stature contracted and dense. Leaves very small, always obtuse, generally emarginate, light green, of a leathery appearance. Leaves of the calyx pubescent. Connectives of the anthers broad and emarginate, ovary densely sericeo-villous. Branches of the style undilated at the apex. Cotyledons unequally auriculate at the base, one of the auricles covering the apex of the large radicle, plumule small.

All agree in the nodding direction of the flowers, the bracteation of the pedicels, the three-celled ovary with 4 ovula to each cell, the tri-partite style, and the comparatively little protected buds.

Although, as I have said, the Assam indigenous plants have a very different appearance from those Chusan, to which however they approach nearer than to the others, there are perhaps sufficient gradations to explain away several of the differences. But whether this will apply to the uniformly large, acuminate, and not unfrequently acute leaves of the Assam plant, to its smooth, or nearly smooth ovary, is more than I would venture to pronounce; and I would be equally reserved, regarding the pubescence of the calyx, the undilated ends of the branches of the style, and the consequent punctiform line of spatulate stigmatic surfaces, the unequal auriculation of the cotyledons, and the inversion in size of the plumule and radicle.

There can be no doubt that if specimens of each of the above, (excepting perhaps the Chinese plants cultivated in Assam, and the Pringitt plants, which are much alike), were to find their way into an Herbarium, and were not known to belong to a genus that has been cultivated from time immemorial, they would be admitted to be distinct by the majority of Botanists.

CAMELLIA.

The Genus is divisible into two Sections.

THEA. Calyce minus imbricato. Gemmis laxe et paucae squamatis.

CAMELLIA. Calyce imbricato in petalis gradatim abiens. Gemmis imbricatis.

1. *Camellia (Thea) Bohea*, Pl. DCII. Fig. I.

Flores in axillis solitarii, pedicellis petiolis duplo fere longioribus, deorsum curvatis medio articulatis, inter medium et apicem cicatric. bractearum notat.

Cal. imbricatus sub 7-sepalus, quarum 2 internis intimoque cæteris, 3-4 plo major valde concava.

Pet. 5 rotundata, concava 2 exterior magis sepalina, dorso viridi-rubescens interior omnino alba.

Pet. 6ta interdum intimo minore.

Stam. 00, æstivatio flexuosa intima subinflexa. Filam. subulatis interiori breviora robustiora. Anth. subquadrata. Connectivum carnosum latum basi medium usque quasi fiss. flam. in fissura parte inferior affix.

Anth. locul. marginatis, centro dehiscent.

Stylus robustus ad medium fere ex apicem 3-sulcatus stamen longiorib. paullo brevior, apice 3-radiatus, radius centro sulcatis, sulco stigmatosa et apice *subcapitata*. stylus infra medium pubescens.

Ovar. infra med. sulcato-angulat. sericeo-pilosum præsertim apice toro glanduloso insidens, ovula 4 perparia collateralia superposita, raphe superi infera, inferi supera, foram. conspicue axin spectant.

Capsula castaneo-brunnea basi calyce nunc e sepalis 5 imbricatis subæqual. rotundatis subcoriacea, parietibus crassiuscule 3-locularis, rounded 3-lobed.

Semen 1 cuique lobo, subglobos. castaneum glabrum læve, hilo magno rotundato, hinc foveolis 3 ob pressione ovulor. abortivor. supra mammilla. minute.

Testa e lamellis 2 extus castan. osseum, intus albidum coriaceo-carnos. vascular layer interjected.

Tegument. interius tenuiss. membranaceus. Cotyledones hæmis phærici, radícula inclusa ob auricul. cotyledon. hilum latus inferius spectans.

1. Branch natural size, 1a mature cauline leaf.
2. Flower in front, 1b bud back of.
3. Do. laterally.
4. Anther back.
5. Do. front.
6. Do. obliquely.
7. Pistillum.
8. Apex of style and the stigmata.
9. Ovarium, 1 cell laid open.

10. Transverse of do.
11. Ovulum under slight pressure.
12. Disposition of two of the ovules of a cell.
13. Fruit, rarely so perfect as this.
14. Seed.
15. Hilum, face of do. the dots are the impressions of the barren ovula.
16. Long section of seed, *a* outer coat of two layers, one hard and bony, the other cellular coriaceous and vascular, *b* exceedingly fine envelope to the seed, *c* cotyledons, *d* radicle.
17. Half an embryo, *i. e.* one cotyledon removed intended to shew the auriculation of the cotyledons.
18. Do. part of cotyledons separated, these are unequal at the base and one is subcucullate.

This drawing was made while making a comparison between the Assam and China Tea plants, and was taken from living plants in the Pringitt garden.

The disposition of the placentæ and ovula are curious, the former are confined to the middle of each cell, being produced outwards into the centre of the cell, and bearing on its apex two ovules; the upper one erect, and lower pendulous. The raphe of both ovula is on that side of the ovulum next the parietes of the cell.

The result when both ovula are matured, is that two anatropous seeds of which one is erect and pendulous, have the radicles pointing exactly towards each other.

Obs. The Chinese plants cultivated in Assam, preserve most of these characters, especially the coriaceous, scarcely acuminate leaves, and pubescent ovary, and non-dilated stigmatic apices.

They tend to pass into the Assam one in elongation, smooth but ciliate sepals and length of style.

The Chusan specimens have the dwarf habit, but the leaves are not more coriaceous than those of the Assam spe-

cimens, some also tend to be lanceolate acuminate, but still retain their bluntness, the calyx is not even ciliate.

The permanent points are, curved pedicels annulate about the centre, blunt leaves, this tendency seems to disappear in the Assam plants, especially those which are caudate acuminate.

The plant from which the above is taken has been introduced into Pringitt's Garden, it there forms a densely branched rather ragged shrub of 3-4 ft. in height.

The leaves are very coriaceous serrated subacuminate, patent recurved convex above, margins subrecurved.

The length is equal to two breadths; flowers solitary or two axillary nodding subsecund, pedicel annulate articule about the middle, with one bractea above.

Calyx shortly pubescent, and ciliate, corolla separating with the stamina, adhering, but separable without laceration.

Bud-scales sericeous, perhaps not exceeding 3, much like a leaf, veneration conduplicate margin once involute.

The differences between it and the Assam plant are in habit, all the parts being here approximated not distant: small, very coriaceous scarcely acuminate leaves, a less bracteate pedicel, pubescent calyx, pubescence of ovarium.

Emarginate connective, stout and shorter style, stigmata punctiform at the apex of the branches.

Direction of the ovula, non-auriculate cotyledons, and non-included radicle, long radicle, and small plumule.

In both the pedicels are annulate, not articulate, the annulus arising from the scar of 2 confluent bractes which in the Tea *open spathiformly*. Pl. DCII. Fig. II.

Assam indigenous Tea Plant.

Stature large, parts distant. Leaves very large, in the dried state black and not of a leathery appearance, very acuminate or cuspidato-acuminate occasionally acute, flowers axillary nodding, pedicel of expanded flower annulate scar about the middle, leaves of the calyx smooth, except the ciliated pubes-

cent margins. Petals with perfect veins, connective of the anthers narrow.

Ovarium very slightly pubescent or quite smooth. Style tripartite, lacinie generally with a recurved apex, and there dilated and stigmatose; ovula one.

Cotyledons inauriculate plumule large.

Assam Chinese imported plants.

Stature smaller, and much more contracted than native Assam plants. Leaves much smaller, pale with a leathery appearance, lanceolate obtusely acuminate. Pedicels, calyx, corolla and stamen as in the Assam plant.

Ovarium densely pubescent. Ovula 4 to each cell, style tripartite subdilated at the apex and stigmatose there.

Fruit not seen.

Chusan plants in the collection.

Very dwarf and contracted leaves tending to be obovate, small, of the black unleathery appearance of the Assam plant. Pedicels and calyx as in that.

Ovarium densely pubescent.

Pringitt plants.

Stature contracted, dense, leaves very small, light-greenish leathery lanceolate always obtuse generally emarginate. Pedicels as before, calyx pubescent. Petals veins not reaching to the margin. Connective dilated emarginate.

Ovarium densely sericeo-villous, style 3-partite. Branches radiating, with a punctiform stigma on the undilated apex of each.

Cotyledons unequally auriculate at the base, one hooded, radicle large, plumula small.

Assam leaves always have a thin appearance, I have not determined the absolute situation of the ovula, from dried specimens, owing to shrinking.

The China plants cultivated in Assam have as complete veins of the petals as the Assam wild plants.

Stigmata various, styles sometimes deeply bipartite, either spathulate at the apex or as in the Pringitt plants, but varies with 4 cells, to the ovary.

2. *Camellia* (*Thea*) *Theifera*, Gr. Pl. DCI. Figs. I. III.

Pedicelli pluri bracteati, bracteis basi latis sursum in sepalis abeuntibus.

Sepala 5-7 rotundata imbricata, petala 5-7 imbricata, ovalia vel rotundata, exteriora bracteis abeuntia, intima petaliformia pluri-venosa, intermedia marginibus membranaceis, basi inter se mediante filamentorum annulo adhærentia.

Stam. 00, hypogyna basin versus coalita inter se et cum petalis leviter cohærentia cæterum distincta.

Filam. filiformia glabra. Anth. introrsæ, basi affixæ biloculares longit. dehiscent. connectivo latiusculo.

Stylus filiformis hirsutiusculus apice tripartit. stigmata totidem reflexa, stylorum apicium facies internas occupant.

Ovarium globosum sursum in stylum productum pilis rigidis brevibus hirsutiusculum, 3-loculare, loculis 4-ovulatis.

Ovula biseriata 2 superiore externa ascendentia, foramen supero, 2 inferiore interne pendula foramine intus et deorsum spectante. Tegument utpote e siccis conspiciere licet unicum, distinctum.

Capsula 3-loba, coriacea, endocarpio tenuissimo membranacea loculicida, septis persistentibus ex axi centrali solutis, lobosum sinibus oppositis, 3-locularis loculis sæpius 1-raro 2 spermis.

Sem. pendula si singula globosa si bina hæmisphærica. Hilum magnum micropyle satis conspicuum, hili latere exterioris contiguum.

Testa coriaceo crustaceo crassiuscula. Tegument inter. membranacea tenuissime inter hoc et testam materies cellulosa vasis spiralibus et ductubus creberrimis interspersa. Semen exalbuminos. Cotyled. hæmisphæricæ. Radicula brevissima supera plumula conspicua.

Raphe externe inconspicua lata, apice seminis geometric apud in ramulo pluries dichotome ramosos dividens, ramis interior apice dichotomis binis extimis lateri exterior ramulos dichotomos emittentibus.

HAB. Upper Assam.

3. *Camellia (Thea) Mastersia* Gr.

Foliis lanceolatis, acuminatis vel cuspidato-acuminatis, coriaceis, serratis, venarum reticulatione inconspicua.

Floribus axillaribus vel terminalibus, solitariis vel 2-4 aggregatis, subsessilibus, ascendentibus, quasi e gemma ovata imbricatim-squamata erumpentibus.

Petalis liberis.

Staminibus subbiseriatis, basi leviter connexis.

Ovario villosissimo, loculis 3 4-ovulatis, stylo 3-partito-stigmatibus linearibus.

HAB. Upper Assam.

Readily I think recognised by the highly bracteate short footstalks of the flowers, by their passing insensibly into the calyx and this again into the corolla.

Contained in a collection presented by Mr. Masters to Capt. Jenkins, by whom with his characteristic liberality it was placed at my disposal.

Making the 4 or 5 species of *Camellia*, indigenous to Assam. I have called it after Mr. Masters.

It may possibly be *Camellia axillaris*, Wall.

4. *Camellia caudata*, Gr. Pl. DCI. Fig. II.

Foliis anguste lanceolatis, caudato-acuminatis, filamentis monadelphis villosus antheris basi insertis.

Omnino ut in præcedente abeuntia bractearum in sepala et sepalorum in petala evidentissime. Filamenta interna distincta hypogyna, annulo hypogyno ovarii basin cingens insertim.

Pollen globoso-subtrigona, stylus obclavatus hirsutissima apice tripartit.

Ovarium sub 6-gonum hirsutum angulis alternis minus pro-

fundis loculis triovulatis, ovulis 2 superioribus collateralibus exterioribus, directio foraminis ut in antecedente.

Septis vix evidentibus sed dehiscentia ostenditum placenta una valvula centro unius semper adhærente. Vasa paginæ interioris testaquæ chartaceo-coriacea omnia spiralia cum interno tegumento-quod tenuissim. secedentibus.

Capsula rotundato-trigona, 1-sperma, 1-loculare, loculis 2 cum ovulis abortient. pressione, capsula exteriori pariete arcte applicitis; semen præcedentis sed minor.

HAB. In collibus Khasyensibus alt. 2500, 4500 ped. (especially on the Bengal side). In collibus Mishmeensibus, non raro ad pedis etiam, gradu lat. 28 descendit.

Stam. 00, basi coalita.

Ovarium 5-loculare, stylis 5 vel distinctis vel parte coalitis, stigmata totidem emarginata, ovula uniseriata.

Fructus 5-ocularis. Semina angulata, aptera ossea.

This Genus has been casually mentioned in my Tea reports, as an undescribed genus of Upper Assam, which has the imbricate peranthium and stamina of Camellia, and to a considerable extent the pistillum and fruit of Malachodendron, so far as I can judge from the description I have of that plant. This, as it seems to afford a direct passage between the subdivision Gordoniæ and the family Camelliæ as they stand in De Candolle's Prodrômus, I have called *Eusynaxis*.

GORDONIA.

HAB. In sylvis collinis et humiliorib. Mergue: Nov. 1834. Altera species, Moulmein vulgata.

3. *Gordonia floribunda*.

Arbor excelsa, 60 pedalis, formosa, cortice cinerea. Rami teretes, ramuli breviter pubescentes. Folia alterna, breviter petiolata, oblongo-lanceolata, acuminata, repanda integra, vel dentata, glabra, subtus glauca, stipulæ lanceolatæ sericeæ, cito deciduæ. Flores solitarii axillares speciosi, albi, odorati. Pedicelli florum inferior longiores, ideoque inflorescentia corymbiformis.

Cal. infer. 5-partitus, sepalis rotundatis, ciliatis.

Cor. gamopetal. rotata, ad basin fere 5-partita. Laciniis rotundato-obovatis.

Stam. 00, ima basin monadelpha et corollæ adnata. Filam. subulat. curvata, lutea. Anth. bilocul. longit. dehiscent. Pollen ovatum læve.

Stylus clavatus, sub-angulat. stigma radiatum, e stigmatibus cuneatis 5 formatum, margine retracta.

Ovarium globos. argenteo-sericeum, 5-locul. dissepimentis axique crassis, ovula 2 in quoque loculo, reniformia pendula. Pl. DC. Fig. II. *a* longitudinal, *b* transverse section of the ovary, *c* ovule.

HAB. In sylvis collinis Moulmein copiosa: *Dec. Jan. Feb. March*, 1834.

DIPTEROSPERMA.

Dipterospermæ sp.

Arbor magna.

Folia ad apices ramulorum conferta cuneato-spathulata vel cuneato-obovata, distanter serratule ascendencia coriacea carnos. Gemmarum squamæ paucæ oblongo-lanceolat. forming. oblong conical terminal buds.

Flores solitariis pedicelli bracti, petiole brevis, longitudine cum flora tota externe cano sericeus.

Cal. imbricatus subtus sepalus, coriaceus, but there is little distinction between the sepals and uppermost bractææ.

Pet. 5 patentia concava rotundata coriaceo-carnos. dorso (partibus internis in æstivat. exceptis) sericeo-pubescent. ope stamina coalita.

Stam. 00, cum petalis secedent. pluriseriata petalis breviora, Anth. oblongæ subversat.

Ovar. super. ovato-conicum. Stylo robusto 5-sulcato apicem stigmat. 5 cuneatis magis radiantib. coronat. 1-loculare! 5 intrans angles wedge-shaped, and 5 alternating in the centre communicate with narrow cells.

Seeds 3 in each cell, large, appense situated near the base, terminating above in a large whitish wing, foramen superior near the base of the wing. The wing is developed from the lower $\frac{1}{2}$ of the raphal face, which is not next the placenta.

Sepals alternate with petals.

Ovules 4 collateral pendulous anatropous produced upwards into a wing. Pl. DCIII. Fig. II.

Terminal scale buds 2 conduplicate vernation of leaf conduplicate-involute.

OBS. Genus indescriptis except its anthers which agree tolerably with those of Godoya.

Certainly distinct from any Ternstroemiaceous genus known to me, it has the flowers of Camellia and appears to differ from Eusynaxis in the complete union of the styles, and 1-locular ovary and winged ovula.

It is I imagine a congener of Roxb. *Camellia axillaris* Bot. Reg. 4 t. 349. Capsula in vol. 8 Notes, is described as woody oblong 5-celled, 5-valved, size of a filbert, with many upright top winged seeds in each cell.

Axillary buds pilose.

ERYTHROCHITON.

GEN. CHAR. Flores dioici, bibracteolati. Cal. inferus profunde 5-partitus. Pet. 5 hypogyna libera, sepalis opposita!! Stam. 00, hypogyna, multiplici serie. Anth. adnatæ, apicibus truncatæ. Ovarium 2-loculare, 4-ovulatum. Styli 2. Stigmata 2, reniformia foliacea. Bacca supera, 2-locularis, 2-4 sperma. Semina pendula arillo? punctulato carnosio inclusa, albuminosa. Embryo curvatus.

Cl. Linneana. Diæcia. Polyandria. Ordo Naturalis. Ternstroemiaceæ.

Habitus. Arbor mediocris foliis stipulatis perennantibus integris, pedunculis extra axillaribus.

Erythrochiton Wallichianum, Gr. Herb. (Mergue) prop. No. 866, Dec. 1834.

In sylvis secus littoram Insulæ Madamacan Mergue proximæ.

Arbor mediocris, dioica; ramulis teretibus. Folia alterna et ad apices ramulorum subverticillatim conferta, oblongo-obovata obtuse et breviter acuminata, integerrima coriacea, parce

1-venosa, supra atro-viridia, infra lutescentia. Petioli basi articulati. Stipulæ? minimæ subulatæ deciduæ. Pedunculi extra axillares, (foliorum abortu?) solitarii 2 unciali flores paulo infra alternatim bibracteolat. Flores majusculi, albi-da odorato facie Camelliæ.

Calyx profunde 5-partitus, laciniis rotundatis æstivatione imbricatis persistentibus.

Petala 5 hypogyna sepalis opposita ovalia subæqualia patentia carnosæ æstivatione imbricata postico reliqua obvolvens, bases versus longitudinaliter rugosa stamina plurima multiplici serie hypogyna, sublibera.

Filamenta brevissima subclavata. Antheræ lineares adnatæ biloculares longitudinaliter dehiscentes directione variæ. Connectivum apice truncatum et dilatatum. Pollen oblongum hinc longitudinaliter sulcatum.

FÆM. Calyx corollaque ut in mare sed multo minus patulæ. Stamina abortiva plurima hypogyna, filiformia plana truncata.

Ovarium Pl. DLXXXV. A. Fig. VII., subglobosum 2-loculare, loculis 2-ovulatis ovula pendula (exapicibus loculorum?) campanulitropa uniformia. Tegumentum duplex foramen hilum prope. Styli 2 brevissima. Stigmata 2 maxima foliacea reniformia, marginibus obtuse inciso-dentatis, anticum et posticum.

Fructus. Bacca exsucca globosa, citri medicæ parvæ magnitudine basi calyce persistenta et subampliata cincta, bilocularis, 2-4 sperma dehiscentia longitudinaliter et irregulariter subquadrivalvis. Semina pendula ab apice placentæ centralis liberæ (funiculis elongatis) arcuata reniformia, arillo? carnosæ rugosulo pulcherrima coccineo tecta. Tegumentum duplex.

Exterius subosseum, interius membranaceum. Albumen semini conforme, carnosum, copiosissimum. Embryo in axi albuminis curvatus, hippocrepidiformis, indivisus! secus peripheriam cum albumina coalitus! Radicula teres longissima? hilum versus spectans. Cotyledones carnosæ coalitæ inter se et cum albumine! Plumula inconspicua.

Genus Euryam Cleveramque intermedium, structura fructus et seminum ad Annesleam accedit, distinctum obformam stigmatum et embryonem indivisum cum albumine coalitum.

I believe that *Hopea eglandulosa* of Roxburgh, which Mr. Colebrooke in a Mss. note, appended to the description in Roxburgh's Mss. synopsis, long ago stated not to belong to *Hopea*, (*Sarcostigma Roxburghii* Wall. Mss.) and which Mr. Brown in his Mss. formerly called *Wahtenbergia*, not only belongs to this order, but will found to be very nearly allied to this genus; of the genus *Sarcostigma*, there appears to be a second species from Sylhet.

Cal. Bot. Garden: *July 15th*, 1835.

ANNESLEA.

Anneslæa fragrans, Pl. DLXXXV. A. Fig. XVII.

Arborea, foliis alternis petiolatis lanceolatis coriaceis, integerrime acutis, floribus corymbosis subumbellatisve, albis terminalibus in pedicello articulatis, ad articulum bracteis 2 ovatis.

Cal. Semi-superus profunde 5-partitus, sepalis ovatis, concavis (2 exterior majorib.) persistentibus coriaceis.

Cor. gamopetala, petalis 5, nempe unguibus latis accretis fauce constricto, limbo connivento 5-partito, laciniis ovatis acutis.

Stam. 00, petalorum unguibus subcohærentia (hypogyna). Filam. brevia complanata. Anth. adnatæ, basi subsagittatæ bilocular longit. dehiscentis. Connectivum ultra antheram in apiculam productum.

Ovarium 2-loculare loculis pauci-ovulatis, ovulis pendulis placenta axilis. Foramen versus hilum.

Carica papyra, Pl. DLXXXIV. Fig. II.

PASSIFLOREÆ.

TRICHODIA.

Arbor foliis alternis (habitu Caseariæ) oblongis late crenulatis. Flores axillares glomeratæ; ferrugineo-viridescentes. Pedicelli basin articulati 3-bracteolati.

Perianth. duplici serie 10 partitum, sepalis 3 exterioribus majoribus, calycinis, squamulæ indefinite simplice serie ex ima basin perianth ortæ lineares villosæ discretæ vel in phalanges coalitæ.

Cal. 5-sepalus, imbricatus corona e squamular. discret. vel coalit. linearium, villosar. simplice serie.

Stam. 5 basi breviter monadelph.

Anth. basi cordatæ profunde, sinu affix. accumbentes. Pollen round, 3-plicate.

Ovaria stipulat. Placentæ bi-ovulat. Styli 3. Stigmata reniform capsula chartacea, 3-valvis, seminib. 2-3 arillatis.

Capsulæ pubescentes erectæ.

Aspectus etiam præsertim capsular Euphorbiaceum.

Habit certainly of *Vareca*, locus naturalis Passifloreæ.

Obs. There is scarcely any difference between the petals and the inner sepals.

From the characters as given in Don, this plant, it would appear to be an undescribed genus, allied to *Paropsia*, and intermediate between the two divisions, the ovaria being stalked, it is also allied by some of its characters to *Modecca*, to *Smethmannia*, in the short corona with a tendency to union, when it would be urceolate.

In the water in which some old anthers had been put, innumerable elliptic bodies occasionally mixed with short moniliform ones were observed, yet to the water itself I do not think these belonged.

Trichodia vareciformis, Gr.

Arbor mediocris.

Ramulo elongate ferrugineo-pubescente.

Fol. altern vernatione involuto-conduplicat. plus minus concavis oblongis, obtuse cuspidatis late crenato-serratis glabris, venis 2-dariis arcuata nexis, interveniis reticulata sub lente minute punctulat. subdiaphan. exstipulat. linea decurrens evanida hinc basis petiole.

Flores in axillis, pauce glomerati, pedicellis basi 3 bracteolatis ibidem articulatis pedicellis petiolos breves excedent.

Cal. 5-sepalus, sepalis lanceolato-ovatis extus ferrugineo pubescente inæqualibus 2 interior duplo minor.

Pet. totidem alternant. sepalis intimis subsimilibus pubescent.

Stam. sterilia 5 filiform. sepalis opposita, arising from immediately under the ovary which is stalked.

Between the stamen and petals is a series of linear very villous bodies.

Ovary subglobos. 3-lobed sulcate pubescent, each lobe terminated by a short subulate pubescent style, stigma 3, long. reniform caducous.

The villous bodies (corona) are either distinct or united into flat lobed phalanges.

The stamens are united at the base into a membranous tube which conceals and adheres to the stalk of the ovary.

Ovar. 1-celled with 3 parietal placentæ, ovula compressed anatropous on short stout funicles, collateral, from the base of placental lines, galeiforme.

Capsula green pubescent rounded 3-lobed terminated by styles, at the base. Perianth and corona unchanged, but browned 1 celled, as it were inflated, endocarp cellular chartaceous.

Seeds 2-3, about $\frac{1}{3}$ way between middle and base of placentæ, compressed $\frac{1}{2}$ covered by arillus which is entire with crenulate margin.

Young testa scrobicular, internally with very many conical verrucæ.

Anth. attached by the middle? bilocular; I am not certain whether the flowers are polygamous, I find on one, the remains of anthers terminating the filament as long as the perianthial leaves.

The calyx leaves are reflexed at the apex, petals are erect.

PASSIFLORA.

Passifloræ sp. Pl. DCV. Fig. IV.

MORINGACEÆ.

HYPERANTHERA.

Hyperanthera moringa, Pl. DCIX. Figs. I. II.

Cal. tubo cyathiforme profunde 5-partit. laciniis, lanceolato-linearibus, parti libera petaloideis patenti-reflexis plusminus concavis. 5to postico.

Cor. 5-petala patalis sepalis sub conformibus spathulat. 2 superior minoribus lateralibusque intermediis ascendentibus 5to majore porrecto antico sepalis alternantia, 1 2 superior bases versus pubescentibus.

Stam. declinat. 10 alterna sterilia sepalis, alterna fertilia majoraque petalis opposit filam subulatis basibus villosis.

Ovarium teres stipitatum villosum. Stylus brevis subclavatus. Stigma truncat. sub excavat. Ovar. 3-sulcatum 1-loculare, pluri-ovulat. ovulis simplice serie placentis 3-linearibus parietalibus affix. foramen hilum prope.

Arbuscula, foliis supra decompositis. Paniculis axillaribus floribus albis. Pollen læve, hinc sulcatum, affinitus cum *Xanthoph.* eglanduloso p. 537.

Obs. I have no notes by me on the structure of *Xanthophyllum*; but if I conjecture rightly the development of the sta-

mina is a good deal analogous to that of *Moringa*, in which if 10 were developed the uppermost would as in *Leguminosæ* be the smallest. The opposition of the two lowermost to the carina may be explained by assuming the obliteration of the proper 1st stamen, and the approximation from pressure of the two normally alternating with the carina, so that they become opposed to it, of this opposition by pressure other instances occur.

Of course this view is only reasoning on the idea, that the petals are properly developed, if not so, then the opposition of these is at once accounted for.

X. flavescens approaches *Moringa* in its pluriovular ovary.

No stipulæ exist, unless they are represented by glands.

The great differences it has with *Leguminosæ* exists in the unilocular anthers, the position of the 5th petal which is anticus, the compound nature of the pistillum, and the nature of the ovula, which in *Leguminosæ* are campulitrope, and in this anatropa, that is the base of the nucleus corresponds to the apparent apex of the ovulum.

The great objection to the idea of DC. that *Moringa* is a constantly tricarpeal *Leguminosa*, I take to be that, if this really were the case, each carpellum would be distinct, since in all cases in which an additional carpella is formed in *Leguminosæ*, it is always so, hence a tricarpeal *Leguminosa* if it ever be found, will be apocarpo-tricarpeal, not as in this genus, syncarpo tricarpeal.

With *Samydaceæ* it has, but little in common, although externally there are no signs indicating ternary composition of the style, yet the shape of its cavity as well as the distribution of its vessels into three fascicles, point this out. The stigma is cup-shaped, or rather none exists, the communication with the interior of the ovary, is free and distinct, and the pollen comes in immediate contact with the mucous conducting tissue by which it is filled; such a structure is compatible with placental stigma, but incom-

patible with a stigma consisting of the denuded apex of the midrib, see also *Viola*, etc.

Hairs simple, those of base of stamina irregular.

- 15a. Do. transverse section.
16. Ovary transverse section.
17. Portion of placenta and ovula in situ.
18. Ovule ad anthesin.
19. Young ovule long section.
20. Ovule after fecundation.
21. Do. long section, *a* testa, *b* inner tegument distinct only towards its neck, *c* nucleus, now nearly completely excavated, *d* chalaza, *e* carunculus formed by an induration of the foramen.
22. Partium situs et alternantio.

The real affinity of this genus is certainly with *Polygalæ* through *Xanthophyllum*, to this Lindley has made an approximation, he refers it to *Parietales*, but next to *Violaceæ*. With *Xanthophyllum*, it has striking resemblances, witness the papillionaceous corolla, unilocular stamina, their direction, etc. and lastly glandulation. It differs from it in the

perigynous corolla and stamina, tricarpeal formation of the ovary, and in the polyspermous fruit.

This genus has a greater degree of affinity to Leguminosæ than Polygalæ in general have, it will form a decided transition between the two orders, chiefly owing to the perigynous insertion of its corolla and stamina.

To the latter Order an additional affinity is pointed out by the obvious tendency of the calyx to assume a petaloid form.

The deciduousness of the petaloid portion of the calyx occurs in *Roydsia* to an equal degree. The stalk of the ovary subsequently assumes the appearance of the remaining portion of ovary, but it is solid. The embryonary sac is of late appearance, I find no trace of it even when the young fruit is nearly a span long.

The glandulation of the leaves is similar to that of some species of *Cassia*, I allude to the stipitate ones found between the folioles, in this genus their presence is not constant.

Bamo: *April 29th*, 1836.

VIOLACEÆ.

VIOLA.

Viola sp. Pl. DCVII. Fig. II.

Subcaulis estolonifera, fol. longe petiolata hastato-cordata, obtusa crenato-dentato, vernatione convolute subtus sæpe purpurascentia, in petiola attenuata. Pedunculi medium versus 2-bracteolat. plano-convexi apice nutantes. Bracteæ subulatae ad pressæ. Flores majusculi cæruleo-purpurei inodori, calcare obtusissimo fusciscente rubro-punctulato.

Sepala lanceolata declinato basin auriculata præsertim 2 antica.

Pet. venosa oblonga, 2 postica ascendentia, antico porrecto, hoc et lateralia 2, qua subascendentia et intus mar-

gines superos versus barbata sunt, basibus albidis, venis atropurpureis lineata.

Antheræ albidæ, apicibus membranaceis circa stylum conum efformantibus aureis, subulis 2 qui a connectivis staminum 2-infimorum originem ducunt et in calcar currunt, viridescentibus. Ovarium antheris circumcinctum, conicum sub 3-gonum, stylus cono apicum inclusus clavatus, apice trigono truncato, stigma foveolum transversum profundum in capite styli orificium ad styli angulum inferum anticumve.

Ovarium 3-gonum angulo tertio postico, ovula 00 rotundato, tegumenta 2 distincto foramen hilum prope, cuique placentæ series 3-4 ovulorum ad sunt.

Capsula calyce immutato persistente suffult. stylo stigmataque sphacelato-apiculata, 1-locularis, loculicida 3-valvis, valvis patentissimis navicularibus hinc utrinque lineatis. Semina lævia pallidissime brunnea, rotundato-obovata, micropyle mammillæformis hilum prope, arillata, arillo albo.

Secus situm pendula transversa vel ascendente, 4-seriata.

Tegument. unicum extus cellulos. intus fibrosum chartaceum fragile, vestit. membrana tenuissime, albumen copiosum carnosum.

Embryo axillis orthotropus, viridescens simplissima.

Radicula teres, obtusiuscula longitudine cotyledonum. Cotyl. planæ foliaceæ raphe opposita. Plumula inconspicua.

Obs. It is difficult to conceive how impregnation takes place, as there is evidently no access for the pollen to the stigma. That this however does take place, I have no doubt from the appearance of the stigma, after the capsule has commenced to enlarge, and after the embryo has become visible, yet in one instance I could not find any remains of tubes or pollen in the stigma or style, there is a membrane however that lines the cavity of the style.

HAB. Burma at Bamo : *April 26th*, 1837.

CRUCIFERÆ.

General Remarks.

In Cruciferæ, we have first the total abortion of all the bractæ, which as Link says, indicates a high irregularity of structure. The sepals and petals present no anomalies, differing only from the usual form in the quaternary number of the sepals, one is anticus, the other posticus, consequently both the petals are lateral; we then have 6 stamens of which the two outermost belong evidently to an outer series and these are opposite the two lateral sepals. The remaining 4, which are the longest, may be considered as opposite the petals, although such is scarcely the exact case.

We then have 4 glands, which I look upon as belonging to one series, placed opposite to each sepal, the two lateral ones being placed within the corresponding filaments. It is my opinion from the above facts, that the two stamina opposite the anticus and posticus sepals are totally deficient, the 2

glands having nothing whatever to do with them. In such a case we have a deficient outer series of stamina: a complete intermediate one, and an abortive inner one represented by glands; all these parts having the regular alternation. The greatest anomaly is presented by the pistillum, the ovary being bilocular, the cells right and left, the placentæ being parietal and anticous, and posticous, mutually connected with the interposition of a cellular plate. But the stigmata are opposite the placenta, or anticous and posticous. I think however that there are indications of the quaternary composition of the style and stigmata, which last are opposite the sepals as they should be. If this be found to be true, then Mr. Lindley's opinion that the carpella are 4, 2 barren, 2 placentiferous anticous and posticous, and the formation will be complete.

TAUSCHERIA.

Tauscheriæ sp. Pl. DCX. Itinerary Notes, p. 247, no. 390.

Planta valde varians, statura uncialis vel pedalis.

Caulis flexuosus, foliis inferioribus pinnatis pinnulis alternis pinnatifidis secus latus inferius subintegris.

Intermedius basi auriculatis, auricula apice lobata cæterum inferioribus similibus, superior ad auriculam reductis ovatis concavis, basi maxima hastato-cordatis obapproximationem auriculare quasi perfoliatis, glaucis.

Æstivat. imbricat. sepalis exterior majoribus.

Racemis nudis terminalibus, pedicellis gracilibus floribus minutis luteis. Calyx basi planus sepalis oblongis exterior majoribus.

Petala 2-3 uno duove sæpius an semper abortiente, spathulata erecta emarginata lutea, longe unguiculata, basi glandula adhærente stipata.

Stam. glandulis nullis interjectis sed basi subincrassat. Anth. basin affixæ biloculares, non adnata.

Ovarium complanatum, oblongo-obcordatum biloculare ovulis solitariis pendulis ex apice loculi stylus brevis stigma capitatum.

Semina (immatura) marginata testa superficie cellulosa solubilis immersionem. Embryo curvatus radícula in dorso cotyledonis replicata.

OBS. A plant very like this is figured in Royle's illust. under name of *Tauscheria desertorum*.

The nature of the simple quasi perfoliate leaves is obvious and is analogous to what takes place in some Umbelliferæ, and in a less degree to certain cases among Mimosæ.

The alternation of the parts is obscure, and the presence of the gland attached to the base of the petals, does not allow us to consider the longer stamina as belonging to the petals but that it is displaced. There is no proof of composition of the outer and larger sepals, or it would be of easy explanation.

There is little doubt, but that several types of structure prevail in the order independent of that of the seed, the value of which has not been yet tested. It is curious, that when three petals alone are formed no extra stamen is developed.

1. Plant.
2. Alabast. lateral view, 2a front view of do.
3. Flower, lateral and front views.
4. Flower, one outer sepal removed, shewing the opposition to it of a longer pair of stamens.
- 4a. Same, all sepals removed.
5. Petal with its basilar gland.
6. Stamina back and front.
- 8, 8. Ovulum and long section.
9. Youngish fruit.
10. Do. long section.
11. Transverse of young seed.
12. Section of young seed shewing that the direction of the cotyledons takes place very early.
13. Situation and alternation of parts, *a* short stamin, *b* sepals, *c* petals and gland, *d* longer stamina.

DRABA.

Drabæ sp. Pl. DCXI. Itinerary Notes, p. 243, no. 364.

1. Plant largest sized specimen.
2. Bud.
3. Flower open.
4. Do. parts of envelopes spread out to shew the relative situation of the stamina, etc.
5. Same calyx removed.
6. Same petals in situ.
7. Back view of anther.
8. Front do. after dehiscence.
9. Section of pistillum through placentæ.
10. Transverse do.
11. Ovulum.
12. Fruit.
13. Do. dehisced.
14. Seed.
15. Do. long section.
16. Embryo laterally.
17. Radical face of do.
18. Partium situs. *a* short stam., *d* long ditto, *b* sepals.

Obs. This species, unless my memory misleads me, is very much like *Draba verna*.

It has all the points of genuine *Cruciferæ*, the glands are irregular generally more or less wanting.

There can be no doubt, I think but that *Cruciferæ* are 8 or even 12-androns. Of the stamens, the outer series is complete, although unequal, the second series is represented by glands, and the third is half complete and represented by two of the longer stamina, which are opposed to the lateral sepals, and although in most cases it is not exactly defined, which of the two are outer or inner, yet cases abundantly occur which suggest that this may arise from pressure, or two of the longer, may belong to two petals, the displace-

ment depending upon causes, which are obvious in some other plants.

In the pistillum there is nothing singular; the opposition of the placentæ to the stigmata can be as satisfactorily accounted for, as the loculicidal dehiscence of certain fruit. The production of the septum is curious, in as much as it points out the extreme tendency in all the most perfect families, to have bilocular fruit.

The natural divisions of Cruciferæ will probably be pointed out by the sensible properties, as much as by any thing else.

CUCURBITACEÆ.

General Remarks.

A unilocular fruit is the type of Cucurbitaceæ, as the ovarium is in some which have a trilocular fruit, unilocular. The attachment of the ovula is parietal in these, and the apparently anomalous result arises from the growth of the placenta inwards towards the axis where they subsequently meet, and outwards among the ovula, and more or less between themselves, although traces of their original distinct separation continue for some time visible. Pl. DCXVI. Fig. VII. *a. c.*

This being the case an unilocular ovarium ought not to ex-

cite our surprise, although the pendulousness of the ovula from the apex of the ovarium, should. This therefore must be introduced into the character of *Actinostemma*. The lateral lobes of the placentæ are alone ovuliferous, the ovula are fixed to their outer surface as regards the carpellary leaf, to the inner as regards the placenta: they are immersed. This is their normal situation, so that judging from the early state of the ovaria, there is nothing anomalous in their situation. The articulation of the pedicels is not a constant character.

The completion of the raphe appears a general character, and this as in some others certainly does not appear to run in the testa or outer integument.

In one instance an exceedingly fine membrane is interposed between the nucleus and inner integument; of the origin of this I am ignorant, not having had an opportunity of examining the ovula until sometime after fecundation. In this too, the tissue immediately surrounding each ovule, is separable with the ovulum, and might be mistaken for an additional integument.

This arilliform integument completely envelopes the seeds, it is perforate alone at its base for the passage of the vessels of the funicle.

In *Coccinia* there is no distinction of coats, nothing to indicate any distinction of parts in the structure of the tube of calyx, all the vessels too are on the same plane; at a very early age the cavity of the ovary will be found occupied by three wedge-shaped placenta, which even now have somewhat the appearance of inverted carpellary leaves. These placenta correspond to as many stigmata, which are quite distinct from each other, and also have an appearance as if slightly folded outwards.

Yet there are grave objections to the adoption of this opinion, in the first place, it implies a simplicity of placenta in a compound ovarium, and it requires that the spaces interposed between the placentæ, constituting the cavities of the

fruit, be considered as spaces between the carpellary leaves, dependent on the inflexion of these, and it also requires that the canals of communication between the stigmatic lines of each leaf and its placentæ shall not run down between the margins of each leaf, but between the margins of contiguous leaves.

The only thing in its favour is the appearance and distinctness of the stigmata, but intimate union between contiguous stigmatic lines may exist at a very early period, we must admit also that the styles are bilobed, but this is not an uncommon structure.

There is nothing perhaps more fixed in Botany than the relation of the two surfaces of the leaf with the stem, all the inversions are satisfactorily explainable. It is difficult I think, to conceive how any inversion of an adherent carpellary leaf can occur.

The whole of our ideas of adherent calyces perhaps require modification. In *Cactus* the cavity of the ovarium is a cavity in the flowering branch, the structure of which is otherwise precisely the same as that of the ordinary branches.

Or the calyx must be considered as highly imbricated, each sepal producing the same bodies in its axillæ as the leaves do, but here also there is nothing whatever to point out, that there is such adhesion, the structure is perfectly homogeneous; on this point too much attention cannot be paid to *Escholtzia*, in which although the sepals are originally hypogynous, they subsequently become lifted up into perigynism by a growth of the torus round the lower part of the ovary. The margin of this is also produced into a calycine rim.

Coccinia is chiefly remarkable for the spurious subdivision of the fruit. The original placentæ are however recognisable at an advanced period, by attending to the direction of the seeds.

Few structures could be more disguised than this, the spaces between the placenta being completely filled up by

dense white tissue and the placentæ themselves being divided into as many partitions as there are seeds.

The ripe fruit is red except at the base, the septa of the placentæ have now a veiny appearance, they separate with the seed, which nevertheless have the peculiar membranous spurious arillus, filled with juice in immediate contact with the seed. The seeds have the usual appearance.

The original cellular placentæ are still traceable, but now consists of a mass of veins, ramified on the septa surrounding each seed.

Such plants as *Triceras*, *Actinostemma* and *Zanonia* will throw light on the true nature of the fruit.

In the Kunkree Cucurbita, the obscuring circumstances take place very early, for even when the bud of the female flower is only $3\frac{1}{2}$ lines long; the Placentæ fill the cavity of the fruit, and have assumed their triangular shape Pl. DCXVII. Fig. 1. *a* true stigma, *b* separable compound lobe, *c* limits of the stigma.

At this period, the resemblance they bear to an inverted leaf is very striking, and the axis of the inner angle is occupied by a developing vascular axis.

The stigmata at this period have acquired the form they are to bear, as well as the cohesion, they separate into 3 lobes, (each of which is *bilobed* along the outer face).

The separable lobes correspond with the placentæ, that is, a line carried up along the inner angle of these will correspond with their axes, impinging on the sinus of their lobes. The perfect stigmata are remarkable enough, a transverse section of each lobe shews that it represents a leaf rolled outward, with its margins curved, and placed in opposition. (See the lower figure.)

The stigmatic surface occupies the whole innerface of the lobe (as respects the axis) and also the whole of the apparent outer surface itself, extending to the margins.

The space formed by the incurvation is not occupied by stigmatic surface, and what is remarkable, presents hairs

similar to those found on the back of the style sparingly and in immense numbers on the tube of the calyx.

These spaces, do not communicate with the placentæ.

The stigmatic canal has the usual structure : it is lined with stigmatic tissue and presents 3 faces, and 3 round angles, which angles correspond with the fissures between the separable lobes.

The styles are very vascular possessing many fascicles, the dilated part presents two converging and diverging from the upper part of the style.

I believe in fact, that the separable lobes of the stigma are in reality compound, that each style is bifid and each division expanded into a lamina curved outwards, and then inwards. These divisions mutually cohere, simulating a lobe of a true stigma.

For the lines of communication with the stigmatic canal alternate with these lobes, the lobes themselves have no central vascular axis which they would have, did they correspond with the midrib of the leaf.

It is curious that if such explanation be correct, the nature of the inflexion of the style, in its expanded part will correspond in a considerable measure with that of the carpellary leaf, as seen in the very young states of *Coccinia indica*.

It follows that if this be the case Dr. Wrights hypothesis cannot be correct, for that necessarily requires that the midrib shall correspond with the axis of the placentæ.

It is not a little remarkable that the apparent inversion of the carpellary leaf should be so continued in the dilated part of the style.

My ideas of the stigmata of this plant (the kunkree) are represented in the annexed diagram, Pl. DCXVII. Fig. II. *a*, *a*, *a* midrib, *b* ditto, *c* direction of the line of convolution, *d* style with vessels, *e* stigma.

In *Gardenia* there is an evident tendency to dilatation of the styles, which are in their upper part battledore-shaped, they are slightly bilobed, the stigmatic tissue occupies the

whole inner face, running down in a gradually widening line from the place where the convolution becomes less.

This plant is worth noticing from the apparent total incorporation of the filaments with the tube of the corolla, as well as from the change in color of this, from green to yellow at the point of attachment of the anthers. Then the whole inner surface of tube is roughish.

[In *Alpina allughas* Pl. DCXVII. Fig. ——— (partis situs, and transverse section of the ovarium, on the right of Fig. V.) there are some appearances as if the labellum was made up of the three stamina that ought to be opposed to the outer perianth.

The two abortive stamina alternate with the anticous of the outer perianth, or in other words, are opposed to the two lower ones of the inner perianth.

If this is correct the lateral inner stamina will be represented by the rounded lateral lobes of the labellum, the anticous one will be marked out by the two dark red lines, and it will be bipartite as in the posticous perfect one.

There is as much reason for supposing the carpellary leaves to be reversed as there is in Cucurbitacea.

Supplementary cells exist in *Funkia*, the habit of which is entirely *Amaryllideous* Pl. DCXVII. Fig. V.

Of the nature of these slit-shaped cells I am not certain, but from the disposition of the central tissue as regards the ovuliferous cells, I am almost disposed to treat them as supplementary.

I must however observe that no trace of them exists in the style, which appears to entirely belong to the fertile ones.

It is also obvious that they may be nothing more than the spaces between the carpellary leaves not filled up, although it would be more likely from analogy to find out such interstitial spaces towards the circumference, than towards the centre.

It is singular that by transmitted light it looks just like the tissue lining the cell, there is a tendency in the slits to pass outwards above near the base of the style, and to become more distant from the outside the further they proceed. They gradually disappear below. At the base, the venation is well shown by the curve of the placentary vessels.

In this, when an outer additional lacinia is developed so also is an additional locule of the ovary.]

LUFFA.

Luffa acutangula.

Scandens scabra, caulis angulatus, fol. ambitu reniformia cordata sub 7-loba, mucronato-dentata basi 5-venia.

Filam. brevia glabra, connectivo in apiculo brevi product. medio supero affixæ. Antheræ extrorsæ, lateraliter dehiscentes, singula vel discreta quoad filam. obliquum uniloculares, aliæ biloculares, æquilateræ; connectivis apice bifidis, omni

barbatæ vel hispidæ, pilis conico-subulatis infra succo flavo turgidis. Pollen flavum 3-angulatum glabrum, Onagraroideum.

Rudiment. Fæm. carnosæ globosa.

Filament composit. fasciculi duo approximatis.

Antheræ compositæ sunt, in vasorum fasciculorum centrale petiolorum cum opposita sunt! fasciculis propriis nullis! anthera discreta simplex.

The truth is however, as I have observed in one case, that the filaments of all have distinct nutriment fascicles, but in the compound ones these are so closely united to the central one of the opposed petal, that they are not distinguishable until they reach the base of the filament.

Of whatever genus this really is, it comes excessively close to *Leucocodon*, which differs only so far as the male flowers, and the fruits are concerned, in all the anthers (3) being bilocular, and in the pollen, I have probably mistaken, the anthers which can scarcely be three, and all bilocular.

HAB. Khasyah Mounts. Ad ripas Kundul: *Sep. 3rd*, 1836.

ZANONIA.

Remarks on the Genus. Pl. DCXVII. Figs. III. VI.

Neither the fruit or flower of *Zanonia* appears to have been described with the requisite accuracy.

In a species lately brought to me, the fruit, is oblong clavate with a flat truncate apex, marked by three lines proceeding from the obscure angles of its margin to the centre. About two lines below the apex is an annular cicatrix, it is one-celled with three large fleshy triangular placenta tapering below, but enlarged above.

The seeds are two in each of the cells formed by the meeting of the placenta in the axis, they are truly pendulous, attached to placenta about opposite the annulus, they are oblong compressed, surrounded by a wing, narrow on the mar-

gins of the body of the seed, but produced at either end into an expansion as long as the body of the seed itself. The seed otherwise has I think the ordinary characteristic structure, except the commissure of the cotyledones is very indistinct, and only to be recognised in a very thin transverse section.

The dehiscence takes place along the 3 lines visible in the flat summit: and the 3 valves so formed, which are internally thick and fleshy at first, and as it were continuous with the placentæ, become by the drying of the tissues, inflexed.

The remarkable points, and such as I would enter in the generic character, are the three large elongated triangular placentæ, the 3-valvular dehiscence of the apex, the inflexion of the valves, binary and winged seeds.

According to Arnott's definition the wing of the seed is considered as of secondary importance, but to me it appears remarkable, not only because I know of no tendency to the formation of a wing in any plant of the order known to me, but because in many, the margin in *Zanonia* so much developed, is channelled or grooved deeply, so that I would rather have expected two wings, one on either side of the actual margin, than such a one as exists in *Zanonia*.

The seeds of cucurbitacea, so far as I know present either a blunt simple margin, or a grooved one, the first may perhaps be taken as an argument against a tendency to be winged, the second would seem to indicate the possibility of the occurrence of two wings, in either case *Zanonia* is remarkable.

Capsula infra apicem annulata, imo apice trivalvis demum valvis inflexis placentæ trigonæ maximæ. Semina two cuique placentæ pendulæ, marginatæ alata.

Fig. III.

1. Very young flower bud.
2. Shews the stigmata and placentæ, the spaces between the

- stigmata corresponding to the narrow slit-shaped spaces between the placentæ.
3. Same laid open, shews the correspondence of the stigmata with the placentæ, *a, a, a* curious processes, forming a sort of annulus of which I am quite ignorant.
 4. Transverse section of the same, there is no peculiarity between it and other young placentæ, except that the placentæ are so approximated as to occupy all the ovary.
 5. Shews correspondence between stigmata and placentæ, in the developed bud, the stigmatic lines are now continuous, *a*, the line of passage inwards of the stigmatic tissue, and between the placentæ.
 6. Shews the same, but in this, what I consider the true stigma is opposite us, *a* line of inflexion.
 7. Transverse section of same with reference to no. 5.

June 16th, 1841.

In *Zanonia* each stigma belongs to its own carpel, but in *Coccinia* it belongs to different carpels, see Pl. DCXVII. Fig. VI. The margins thus stigmatic have no connection necessarily with the placenta.

Zanonia clavigera, Pl. DCXVII. Fig. IV.

Flores (fæminei) virides, ovarii clavata more fere Caryophyllorum) articulato in pendicellum brevissimum suffultum bractea obsoleta.

Sepala 3, raro 4, 2 binatim composita, paullo majora, bivenia, tertium univenium, semi-rotundata marcescent. Petala 5, carnosæ, ochroleuca intus papillosa cordato-ovata æstivatione valvata acutiuscula caduca.

Stam. sterilia glandiformia 5, situ parum regularia (not always present, when so, they may be taken into account for ascertaining the situation of the sepals, to which they will be opposite.)

Ovarium obsolete angulatum glaberrimum $\frac{4}{5}$ inferior, $\frac{1}{5}$ above the attachment of the floral envelopes, trigonum, et planum, lineis tribus ex angulis ad centrum currentibus notatum.

These lines run into styles, diverging towards their apices, the space occupied by stigmatic tissue.

Styli ad angulos siti, brevissime, stigmata totidem exactly-like short ram's horns inflexed.

Ov. triloculare, ovula cujusque locula bina, pendula ab apice, 1 utrinque fissura (incompletæ junctionis) ordinis, memb. inter collum proficiens, the cell is opposite the flat faces not practically existing, owing to the size of the placenta, which starting from a narrow attachment at the angles, fill the whole cavity, being besides mutually closely adhering. This triangular mass, so resulting, presents traces of composition in the shape of the usual lines* indicating placentary composition, which lines are alternate with the angles. Towards the points of union in the axis, each presents a transverse subreniform mark of vascular fibrous tissue.

At the apex of these composition lines are found the ovula, one on either side, a short distance below the base of the styles, pendulous, closely appressed to the mass of placenta.† Now in this case it would seem that the cells of the ovarium correspond as usual with the styles, that the ovula are attached to the margins of the placenta, which are produced inwards into a confluent mass, the study of the development will alone shew whether this is the proper explanation, or whether the placenta in this are continuations of the axis, united along certain lines to the carpel leaves.

Or we may take the parts between the styles as the carpel leaves, which also appear to be indicated by the lines in the vertex of the ovarium.

In this case, the placenta will have contracted an adhesion with the midrib or central line of the leaf, and the stigmata of each carpellum will be completely separated.

* These lines correspond with the styles, and so with the stigmata, consequently the centre of the cells of the ovarium corresponds with the styles.

† Three lines of composition remaining instead of six, and these lines shewing the lines of union of the placenta of the same carpellum, the others being quite deficient.

I have no doubt, but that the styles and stigmata occupy their usual place *i. e.* the dorsum of the leaf, and that the furrow running along the venter of the style, which dilates above, giving exit to the stigmatic tissue, is the ventral suture, and that the ovula are attached to the margins of this, at the apex of the cavity of the ovary, and that below this, the placentæ of the same carpel are united, but still present traces of composition, and that the only anomaly, if it is one, is that there is no trace of the composition of the placentæ of the contiguous carpels.

In this case the situation of the vasc. bundles of placental mass is proper, that is belonging to the margins, (being compound necessarily.)

If the other explanation that the spaces between the styles are the carpel leaves, be assumed, then the line of inflection ceases to be marginal, or rather is not along the axis of the leaf, as is always the case, and the placentæ arise from the midrib, and bear the ovula, which would be all quite contrary to analogy; and what is still more important, the stigmatic tissues, in this case compound, would have no theoretical connection even in direction with the ovula or placentæ, but a line continued downward would traverse the centre of the ovarial cell.

Pl. DCXVII. Fig. IV.

1. Female flower.
2. Same petals removed or fallen off.
3. Apex of female flower seen vertically, shews the composition of the sepal, the sterile stamens and appearance of the apex of ovarium. The situation of the 5th, or simple sepal not ascertained properly.
4. Long section of upper part ovarium, *a* fissure of marginal non-cohesion, *b* cell, *c* ovulum.
5. One of the cells cut away up the back of the style, shews the fissure of non-cohesion, and situation of ovula.

6. Transverse section of ovarium, corresponding in situation with fig. 3, close to insertion of envelopes.
7. Another of same much lower down, and below the ovula.
8. An ovulum.
9. The same outer tegument for the most part removed.

ACTINOSTEMMA.

Pls. DCXIV. DCXV.

Planta dioica. Herbacea annua scandens.

Caules elongati, angulati sulcati, crassitæ pennæ corvinæ, parce puberuli, tenera succulenta plantæ fæminæ multo magis evoluta.

Folia alterna longiuscula petiolata, exstipulata, juniora cordato-hastata, 3-loba, lobis lateralibus, subbilobatis, grosse dentata, dentibus mucrona terminalis, dentibus basilaribus singulis, vel binis utrinque glanduliferis, acuminata, saturato-viridia utrinque ad venas puberulo hirta, basi palmata 3-venia, venis lateralibus cito bifurcatis secundariis inconspicuis mutuo arcuatim anastomosantibus, pagina cæterum areolata reticulata, infera tantum stomatosa.

Petioli sesuncialis supra canaliculato-puberula.

Cirrho solitarii hinc basi petioli quasi adjecto, spiraliter torta, apice bipartita.

Inflorescentia utriusque sexus axillaris, mascula racemoso-paniculata. Paniculis filiformibus elongatis folia fulciant aliquoties excedentibus ab ima basin ramosis, ramo sæpe æquante, sulcatis puberulis, ramis divaricatis racemosa plurifloris.

Bractea subulata minuta ad basin cujusque divisionis et cujusque pedicelli.

Pedicelli medium infra articulati, si solitarii semper hinc basin rudimenta alternis stipata, puberula parte infra articulum persistente.

Flores caduci, inconspicui, viridii lutescentes, inodori, evolutione centrifugi.

Cal. rotatus profunde 5-partitus, laciniis basi obsolete saccatis, lineari-lanceolatis acuminatissimis patentissimis, acuminib. subrecurvis, extus puberulis, univeniis, æstivatione valvatis.

Pet. 5 sepalis alternantia, fundo calycis inserta breviter unguiculata e basi lanceolata acuminatissima patentissima, univenia, æstivatione subimbricata, ungue et limbi ima basin cum calyce cohærente, marginibus ut etiam sepalorum glanduloso-denticulatis.

Stam. 5 imo fundo calycis inserta, omnino discreta, sepalis opposita, inclusa. Filamenta breviuscula filiformia.

Connectivum glanduloso-papulosum, viride. Antheræ adnatæ uniloculares extrorsæ, longitudinaliter dehiscentes.

Pollen luteum lanceolatum plicatum, immersum globosum granulosum; plicis expansis membrana interna apparent.

Rudiment fæmin nullum.

Flores fæminei racemosi, racemis paucifloris sæpius unifloris, flora unico in omnibus tantum evoluto. Pedicelli florem prope articulata, bractæ ut in mare Calycis tubus subglobosus verrucosus, limbus corollaque ut in mare sed lacinia magis reflexæ, sæpius caduca interdum marcescunt et serius labuntur.

Stamina ut in mare sed minora interdum castrata.

Ovaria 2, 3 inferum, parte libera conica verrucosula, 1-loculare. Placentæ punctiformes, nulla septa.

Orula 2, 4, sæpius 4 pendula ab apicem loculi, si 4 bina ab utroque latere. Foramen superum hilum prope. Tegumenta bina distincta, interum inclusum.

Stylus crassus brevis, leviter complanatus demum ampliatus, parce puberulus, stigmata bina approximata hippocrepidiformia, vasorum fasciculi plures, 3, 4 minores circa atus externis unici majores centrales dispositi, styli centrum omnino evasculosum.

Fructus pendulus, (pedicello infra articulam gracili, supra

incrassato, petiolo brevior) ovatus obtusissimus apicem versus leviter attenuatus, apice stigmata reliquis minimas sphaelatus gerens, aculeis viridibus complanatis et præsertim annulum infra valde echinat. apice subglaber, tactu lævi ad annulum circumscissus! unilocularis 2, 4 spermus, mesocarpium celluloso spongiosum crassum album, rugoso.

Endocarpium cellulo-membranaceum tenuissimum, e cellulis angustis quam maxime irregularibus forma situque conflatis, superfici ei intus rugosa.

Placentæ obsoletissimæ, septa sæpius nulla, rarius obsoletissima.

Semina 2, 4 sæpius, 4 pendula atro-brunnea, demum brunnescente tactu saponacea, valde complanata, superficie valde irregulare rugosaque hinc utrinque profunde sulcatis, marginibus varie dentatis, hilum minima micropyle parum conspicua.

Testa fragilis, diploe alba cellulosa, margines versus crassa.

Tegumentum interius celluloso-spongiosum album superficue venoso-reticulatum et exaratum, venis e raphe fere completa utrinque ramos exserente ortis, irregulariter divisus sæpius distinctos, interdum anastomosantes, inferioribus cæteris duplo longioribus.

Tegumenta 3tiam (nucleare) tenuissimum celluloso-membranaceum læve, hinc apice longiuscula apiculato excepto, adnatum.

Albumen nullum.

Embryo inversus, quoad fructu, orthotropus quoad semen.

Cotyledons ovals carnosæ plano-convexiusculæ, faciebus laterioribus seminis parallelæ, ideoque raphi alternantes. Radicula conica acuta breviuscula, basi utrinque breviter auriculat. supra hilum prope.

Plumula conspicua.

Adest etiam membrana tenuissime inter cotyledones, ob cotyledones initio divaricatissima.

This membrane is nothing but the originally cellular portion of the embryonary sac that intervenes necessarily be-

tween the cotyledons, which are in their young stages very divarcate.

Huic genus proximum constituit planta cujus mas. hucusque tantum visa. Scandens tener, petiolis canaliculatis marginibus canaliculæ dense ciliatis, foliis ternatis, foliolis lateralibus binatim divisis, cirrhis hinc petiolis adnatis simplicibus vel bipartitis, floribus masculis paniculatis, paniculis compositis folia sæpius longe excedentibus, calyce 5-partito, laciniis brevibus obtusis. Petalis lanceolatis acuminatissimis, staminibus monadelphis, filamentis omnino connatis, antheris unilocularib.

Pl. DCXV.

Stam rudim 0, in flora fœmineo. Styli 2, $\frac{1}{2}$ sepalis $\frac{1}{2}$ petalis opposit. 3tio petalo omnino opposito.

Obs. On what principle is an anther like this explainable? The bilocillate form is riducible to the genuine bilocular (quadrilocellate) by assuming the secondary septa to be deficient.

And the only manner I know to reduce the genuine unilocular anther to the ordinary type, is to assume the antheral leaflet margins as entirely coalescent.

The true modification of anthers requires examination. It is at once obvious, that a quadrilocellate anther cannot be well explained if we assume the lines of dehiscence as corresponding to the lines of inflection of the margins of the leaf. To explain them in that way, 4 leaflets are required for each and all on the same plane, which is contrary to analogy.

The septa are the last things formed probably by having a different origin and analogy.

GUTTIFERÆ.

CALOPHYLLUM.

1. *Calophylli* sp.

Calophyllum, glabrum gemmis ferrugineis puber except. fol. oblonga, in petioli attenuata obtusissime margine undulata, racemis sæpius 2 3 fasciculatis, foliis dupl. triplo brevior, floribus suboppositis, sepal. petal. duplo minorib.

HAB. Assam at Suddyah: Jan. 9th, 1836.

FLACOURTIA.

Flacourtia edulis.

Fruit the size of a large cherry, annular at the base and with the remains of the perianth: apex depressed, umbilicate surrounded with the persistent unchanged styles and stigmata smooth, externally reddish with green streaks, baccate with as many cells as there are styles, each filled with pulp in which, the solitary and binary pendulous seeds nestle.

Seeds much compressed, testa thick indurated nearly bony, inner tegument very thin brownish membranaceous.

Albumen copious fleshy. Embryo with the radicle next the hilum, and consequently superior, with flat foliaceous cotyledons cordate at the base. Plumula inconspicua.

HAB. Malacca, habitus foliatio armat. Flacourtiae, fl. masc. Getonia.

Evidently akin to the S. African genus *Dovyalis* vide Arnott Journal Botany, Vol. III, p. 251.

LORANTHACEÆ.

General Remarks.

There can I think be very little doubt that the following Orders form a very natural group, Santalaceæ, Loranthaceæ, Olacineæ.

The presence or absence of the corolla cannot be admitted as a valid objection, because although most Loranthaceæ have a highly developed corolla, there is no trace of it in *Viscum*.

Olax, although it has a superior fruit, and so like in appearance to an inferior one, that dissection must be resorted to, to detect the difference.

Olacineæ are widely displaced by all authors except the illustrious Brown, who long ago pointed out its great affinity to Santalaceæ.

Its affinities with Aurantiaceæ and Sapotaceæ are purely imaginary. The Order points out the tendency that exists to suppression of part or the whole of the outer series of stamina, which is so complete in some Santalaceæ, and all Loranthaceæ: what is the cause of the presence of a glandular disk so frequently among Epigynous Orders.

No vessels exist in the corolla of *Schæpfia* opposite the sinuses. The style has 3 vascular fascicles, it will be worth while to apply the test of situation of carpella relative to the calyx, or at least supposed calyx of many plants, if these have really calyces, the carpella will alternate with them, owing to the law, that no two organs of similar denominations can be opposed to each other.

The above Orders agree in the following remarkable parti-

culars, valvular æstivation, opposition of stamina, composition of ovarium, structure of placentæ and reduction of the usual parts of an ovulum; this being carried to its maximum in Loranthaceæ, the differences of albuminous seeds are non-adhesion of calyx in one, but this may be explained away, and the development of corolla, which as it is irregular, is of less account.

Santalaceæ are usually supposed very nearly akin to Elæagneæ and other Tubiferous classes, but the affinity may not perhaps be so very close to Proteaceæ. Thymeleæ, and Elæagneæ have simple ovaria; a sign of much consequence. Lindley places Anthobolææ among Thymeleæ on account of its superior fruit, but as it agrees otherwise with Santalaceæ, it will probably serve to point out, that the ideas I have above noted are very natural.

Choretrum is stated by Brown to have a very minute 5-partite calyx, I say from analogy that its perianth is more colored than those in which no calyculæ exists. Quinchamalium has an urceolate bractea, totally distinct from the ovary, and this is rightly considered by Brown as an argument in favour of the perianth of the related orders being calycine. This instance I take to be most important, for it explains away the greater part of the anomalies, for the bractea cuculliformis of Quinchamalium is obviously akin to the calyculæ of Loranthaceæ, the same of Schæpfia, the same perhaps of Olacineæ.

As Brown says it is probable that the perianth is calycine not corolline, because of the valvate æstivation, an uncommon occurrence among truly petalous orders. Then he notices Viscum and Loranthus.

The look of the perianth of Schæpfia is not at an early period continuous with the calyculæ, if it be strictly so, it must be calycine.

A genuine calyx must be continuous with the outer structure of the part of which it is a development, if it be not,

it is corolline, belonging to the glandular system; see Brown's Obs. on the analogy of the perianth of *Quisqualis* and *Combretum*.

LORANTHUS.

Loranthus concavifolium Gr. Scurrulæ sect.

Attachment simple, plant pendulous.

Tota planta furfuraceo pubescent præsertim fol. subtus furfura e pilis ramosis pallida.

Fol. alterna vel subopposita, basin subtus nitentibus et senioribus glabratis, fragile, brittle, cordate, ovato-oblonga sæpius concava, integra obtusa carnosio-coriacea, venis secundariis inconspicuis.

Novellis albidis, novissimis ferrugineis, vernatio concavo-conduplicata, racemis subcymiforme aggregatis in axillis velustioribus, foliis brevior, fl. l-bracteata basin ferrugin pilis cinct.

Calyx clavatus ore truncato extus ferrug. tube of corolla sub oval-shaped compressed above near the calyx gibbous (curved upwards) estivation of bud much greater, bud subcylindric except the knobbed apex.

Corolla 4-fida, fissura postice profundior, laciniis erecto-incurvis pallide viridescens.

Filam. complanata sursum latiora ad exertionem angustata, rubror sanguinea. Anth subovatæ, Stylus longitud. Stam. Stigma capitat.

Fructus (junior) clavata.

HAB. Malacca, in Rhizophoreis mangrove woods on Sonneratia.

From descriptions it is impossible to determine, it approaches closely both to *L. scurrula* and *chinensis*, from which it differs in single attachment, leaves subalternate concave, coriaceous brittle above shining, and when mature very smooth, in the flowers pale inside, laciniis inflexis.

Dicatur *L. concavifolium*, if this be found a permanent mark, for I have only seen one specimen.

The phenomena of fecundation are those of *L. bicolor*. the sacs are of great tenuity, the cavity of the ovarium appears blocked up, the embryo base is on a level with the base of the cotyledons.

2. *Loranthus farinosus*, Pl. DCXX., or *L. incarnatus*, Jack, for the young shoots and leaves are covered with ferruginous pubescence, although otherwise it does not agree with his description.

The embryo sacs reach up the style a good way nearly to the stigma, often, and generally it presents the same phenomena as *L. bicolor*. The chief anomaly consists in the soft mucilaginous nature of the cells first developed, their adhesion to the embryonic mass, the preponderance of this body at an early period, the exceeding distinctness of the inner tubes, not only separating easily from the sacs, but from each other. The embryonic tissues appear to commence from the inner tubes at the termination of the sacs. It presents the same development of cellular tissue from unfecundated sacs, the same engagement of 2 pollen tubes, the abortion of some of the sacs occasionally, the same fundus to the ovarium, the same composition of the embryonic mass.

The young fruit is hard, the fibrous or hard outer layer being produced inwards in a ruminant manner.

The embryo sacs become enlarged subsequently, but no albumen seems to be formed in their cells. *L. oleoides*, presents the same phenomena as *L. globosus*.

Pl. DCXX. Fig. I.

1. Raceme and alabastrum of *Lor. farinosus* or *incarnatus*.
2. Flower, slightly increased.
3. Upper part of perianth laid open.
4. Base of pistillum and its bractea.
5. Stigma.
6. Long double section of ovarium during expansion.
7. Lower parts of style of ditto with two embryo sacs.
- 7a. Head of one of the embryo sacs of the same ovarium.

8. Long double section of ovary after the fall of perianth.
- 8a. The seed, developing of the same.
- 8b. More magnified two of the inner tubes have separated from their sacs which were torn away.
9. Embryo more developed, no longer adheres to the cellular tissue, grown from the sac.

The same Pl. DCXX. Fig. II.

Valde affinis *L. coccineo*.

Obs. In *Loranthus pentapetalus* the circumstances attendant on the development of an albumen, as well as of the embryo are obscure, I have seen tubes entering into the head of the sac, and I have after the fall of the style found them in the ovarial portion of the same organ, but after they are scarcely detectable up to a period when the albumen has attained a considerable size, and then what is very remarkable, the funicle of the embryo consists for the whole of its upper part, of a simple tube, other less remarkable anomalies consist in the ease with which the albumen, even from its commencement almost separates from the sacs, and perhaps in the lateness in which the tubes, and the single funicle of the embryo become invested with a proper membrane, or is really tubular.

Pl. DCXXV. Fig. I. Even at this period which is first after the fall of the style, the cellular mass appears quite free, it is invariably terminated by a single conical cell.

The sacs are now withered, adhere closely to parietes of the cell.

They are attached to the apex of the mass, although from the production of the cells upwards, this is obscured, and even becomes somewhat lateral. Subsequently the inner tubes exist in some, after which they reach to the mass, the y

are more obscure in this, than in any instance I have yet met with.

I have not been able to trace them into the mass, although the lax smaller cellular tissue at the apex of this, obviously represents the embryo as it exists in others of same type, and this is the more remarkable because the more developed embryo I have observed sometime back to be most distinctly filamento-funicular. *a* green, *b* red, *c c* sac.

Fig. II. Cavity occupied by a cellular body, above with large simple empty cells, below with more numerous, and more close with granules. This body is connected above with at least some of the sacs.

Composed of dense red cutis, the dense green rather thick tissue, the rest white first a layer thickest below the young viscum curved and thickest above the dense central tissue.

In this instance one tube was seen applied to the cellular mass, but no tubes were seen inside it, nor were any seen in the mass itself.

Fig. III. Cellular mass upper $\frac{1}{3}$ laxly cellular cells large in 2 series lower, two thirds densely cellular uniform with an opaque central line caused by the embryo.

This embryo consists to the top of a long clavate irregular filament containing green globules the large and short cells intervene, then the long tissue of the base of the embryo, the collateral tissue only commencing.

The filament does not reach throughout the mass but ceases at the denser tissue, it never presents traces of composition. *a* opaque cells, *b* transparent, *c* green, *d* red.

The anomalies are great, upwards the production of cellular tissue, in the great size of young albumen before the embryo appears, its lateral attachment, in the late appearance of the inner tubes, and in the simple filament of suspension.

Fig. IV. In this instance a flasque lobe without tubes was attached to one side, the mass had the usual shape. In the centre $\frac{1}{250}$ shewed 2 fine tubes which projected beyond the

lower end, and of these one was swollen into a ball. The point whence these tubes originated was not seen.

Their observation is very obscure, for in a structure of this sort if they run along the intercellular lines, they can scarcely be seen.

Fig. V. The nipple is very evident, and terminates the central column of amylaceous tissue, its apex corresponds with the lower orifice of the stigmatic canal, its appearance is altogether nucleary.

This nipple is visible up to a period just antecedent to opening of the flower, it has the same shape but appears to be hollow. *a* vessels, *b* fuscous, *c d* reddish, *e* green, *f* opaque.

If the sacs are developed first in the ovary, as I think they would be, *Loranthus* becomes an instance of a nucleus exerting several embryo sacs, unless indeed the sacs pass up into the style, round its base, and so avoid perforating the cone.

Fig. VI. No cellular mass is produced before the fall of the style, and no inner tubes in the lower part or ovarial part of the sacs, no viscum.

It is difficult to examine the sacs at this period, as the central columnar tissue is tough and opaque amylaceous granules.

All the sacs at least do not reach to the fundus of the central amylaceous tissue.

The unequal extent of the sacs may perhaps give rise in some measure of the lateral apex of the funicle.

Even after this and before any visible enlargement, the sacs remain unchanged with the exception of shewing evidences of the inner tubes becoming in iodine columns of grume, without proper membrane and not extending into the dilated part of the sac.

4. *Loranthus coccineus*, Pl. DCXXVI.

Ramuli papillos. fol. alter. mediocre petiolatis, coriaceis costa excepta aveniis, fuces viridescence e basi cordati inæquilateraliter oblongo-ovata, obtusa ima apicem rotundato obconduplicatio gradatim concava.

Racemi axillares, fol. breviora spicifor. undique florigera.

Pedicelli breves, declinati alabastror. transversi vel ascendent apice subflor. 1-bracteate.

Alabastrum adpressum raceme axin infra medium 4 gonum, supra subteretes.

Perianth ad medium 4-partatum, laciniae patentibus, an recurvis, corollam urceolatam tubum angulatum, apice angustat. simulans extus, brunneo-coccineum intus vividum coccineum, extus pilis stellatis vestit., in reality it is composed of 4 pieces, with a broad subtriangular concave base, then a narrow part (at the faux) the margins are here rugose and folded over the filament which is inserted here.

Filam cylindracea vivide coccinea perianth lacin. paullo brevius, anth. oblongae breves adnatæ.

Calyces tubus subcylindraceous ore pallulum angustato, subintegro, omnino pilis ferrugineis stellatis squamato-furfura, stylus coccineus clavatus, stigma capitato discoid. coccineum, perianth lacin æquans.

Fruit shaped like a florence flask, nempe e basi rotundata, gradatim attenuata apice subcylindraceo, extus more calycis sed distantius furfurac.

Viscum albidum copiosum, semen erectum conico-4-gonum angulis hispidus in setus albidus longe product, basi induratum, the space between the prolongations filled with viscous resin in which the green radicle nidulates.

Albumen album carnosum confined to the indurated base, cotyledon, cylindraceus albumin $\frac{1}{2}$ brevior.

Rad. maxima sphaerica exsert.

Embryo altogether green.

Obs. It is closely allied to *Loranthus pentapetalus*, fol. alternis e basin inæquilateraliter cordato-ovata, per obtusa coriacea evenia. Racemis axillaribus speciform, solitariis vel fasciculatis, floribus 1-bracteatis pedicellas declinatus 4-meris, stylo cylindracea. Bacca e basi ovata, in collum attenuata. Semen 4 gonum, hirtum 4 setigera, indurato.

It belongs to the same group with *L. oleoides*, *farinosus* and *pentapetalus*, and is the same in physiology with *L. bicolor*, viz., sacs extended up the style, albumen developed from their anterior ends.

The inner viscum is first formed, *i. e.* that which conceals the naked radicle, while this is developing, the tissue on the lines of the perianth and its 4 horns becomes indurated, and the outer viscum becomes developed, at first between the horns and the green tissue, then extending downwards and ultimately extending all round the pericarp and its horns.

The cotyledons are 3, which is another point of affinity with *Santalaceæ*.

The part of the embryo first formed is, I think radicle, if so it becomes pushed upwards by the growth of the cotyledons downwards, this point is worth examining.

5. *Loranthus obovatus* Gr.

Ramulis compressis junioribus, etiam glabris, fol. opposit. breve petiolatis cuneato-obovatis, coriaceis glabris læte emarginatis, venis secundariis supra subdistinct.

Shortly after the fall of the corolla which I think takes place quickly carrying with it ? the style, a double long section presents the following appearances :

The cicatrix of the style is made up of browned dislocated cells, and beyond it projects to a considerable distance, slender tubes which are the boyaux.

The sacs about the middle of the section gives birth to a cellular mass, the walls of the cavity surrounding which are distinctly sphacelate.

Below this, there is a common somewhat obpyriform cavity, the margins of which are very opaque, this is filled by the convoluted prolongations of the tubes beyond the cellular mass, and below by the embryo, which is preponderately developed.

The first changes in the appearances after impregnation consist in a long section of irregular opaque lines along the course of the sacs, these lines have brownish edges, and are irregularly flexuose, transparent along the centre, where they look cellularly subdivided, then, I imagine by the disappearance of the tissue around each, coalesce into one cavity, when the appearances are such as I have described above.

It is only through about the lower $\frac{1}{2}$ of the central tissue that these enlarged and irregular lines are evident, this is easily accounted for.

I believe the sacs can develope (4) oblong cells from the apex independent of fecundation.

Pl. DCXXIII. Fig. III.

Bud 2 lines long. The style presents in its lower part at least a slit-like cavity which extends below its base into the ovarium, the fundus is occupied by a conical-shaped process of mucilagino cellular tissue. Iodine at this period does not exert its particular amylaceous action on any part, but the nipple and the sides of the canal of style are more darkly fuscous than the rest.

Bud $3\frac{1}{2}$ lines. The nipple is more developed. Iodine now violets in several lines, which affect also the nipple at its base, but only partially compared with the violetting along the other tissue of interior of ovary.

Violetting also takes place at the extreme base of ovarial tissue, but in a slighter degree.

The appearance of the violetting lines is such as would suggest the exertion of several sacs ascending from the base of the nipple.

Yet I believe that this arises merely from the contiguity of the lines to this body, as the lines on dissection appear to pass by it.

Five lines long. The nipple is now very hard to free.

Iodine causes the same violetting which extends upward a little way into the style, and below has a tendency to pass beyond the base of the nipple, reaching almost if not quite but in a faint line to the basilar violetted spot.

No sacs appear to exist at this period.

The part which corresponds to the calyculus is not much fused by iodine, but retains a greenish appearance.

The rest of the base of the flower is a homogeneous mass percursed by vascular bundles.

$10\frac{1}{4}$ lines long.

Nipple scarcely if at all detectable, central tissue whitish gorged with granules, percursed by 5-6 fuscous lines, which now reach lower down than they did before.

Iodine now violet the whole of this, most intensely however along the lines of the sacs. The base is now when iodined indistinguishable from the rest.

Sacs exist at this period, but I am ignorant how far they extend upwards.

A long section at this period, shows the slit of style not to extend to its base.

A transverse section at this period iodined shows a small central space unvioletted, around which are 6 violetted spots, towards the base of the flower confluent, above more and more distinct, they are in the direction seen to be opposite the lobes of the epigynous gland.

Towards the apex rather oblique, *a* calyculus, *b* part of base of perianth, *c* part of epigynous gland.

The lobes of this are alternate with the lobes of the other fig. towards the base, as is shewn by the situation of the bundles of vessels.

The violet dots in a bud, 3 lines long are only visible towards the epigynous gland, below, the tissue is quite homogeneous.

If it really is the case that the sacs are developed from above downwards, and that they subsequently extend below the base of the nipple, it may be considered as conclusive that the nipple is merely an elevation of the paries of the ovary, and has nothing apparently in common with an ovulum.

After repeated examinations I can make nothing out of this from the time, the nipple appears to become adherent. The style separates at the point where the open canal terminates; here it seems to be solid.

At expansion, the ovary may I think be described as solid containing 5 or 6, gut-like embryo sacs, imbedded in the

central tissue, this is particularly the case, on a transverse section, at this period I can find no traces of the nipple.

In no stage have I seen any thing like the prolongation from the nipple of *Loranthus bicolor*.

The appearance of the nipple in its earlier stages are similar to the placenta of *Santalum Osyris* so as to point out the probability of its being a similar organ.

The same Loranthus leucosiphon, Gr. Pl. DCXXII.

1a. Lateral bractes entirely enclosing young flower.

b. Calyculus.

c. Perianth.

d. Stamen.

e. Pistillum.

f. Its cavity.

The pistillum is at this period greenish, the stigmatiferous portion of the style exceeds a good deal the remainder, and is even now celluloso-papulose. The canal of the style extends throughout its length, and terminates below in a triangular small cavity with a flattish fundus, which is on a line with the line of attachment of the perianth and the stamina.

The whole cavity of the pistillum is rendered opaque by air.

It is evident that at this period the whole pistillum is superior, even with regard to the perianth and stamina, but much more so with regard to the calyculus, the line of whose attachment is to be perhaps considered a line, midway between the exertion of its inner and outer surfaces.

2. Double long section of ovarium etc. 5 lines long.

a. Calyculus.

b. Perianth segments, now inconduplicate.

c. Canal of the style, the lower line points to its termination, I think from adhesion.

d. The closed up part of the same, the lower line marks out its termination.

e. The part now violetted by Iodine, there is perhaps a tendency to less action along the centre, as at *ff*.

At this period there is nothing satisfactory detectable of the nipple, although I have seen appearances as if it had become elongated, the apex of the neck, reaching to the point where the canal of the style appears to become closed.

3. Double transverse section of the same.

The calyculus is distinctly marked out, underneath its cutis is a black line of opaque tissue to which succeeds a double row of rather large transversely arranged cells.

a. Calyculus.

b. A thick layer of dense tissue greenish in its natural state.

c. Sub hexangular in outline.

c, d, b. Vascular fascicles surrounded as usual by uncolored fibrous tissue.

e. Greenish tissue occupying the greater part of the inner circle.

f. Vascular fascicles of the ovarium itself.

g. Six ovate opaque spots which I take to represent the situation of the sacs, and which are violetted by iodine in a confluent manner as pointed out by the blue lines.

h. A central cellular spot.

4. Double long section of flower bud, $4\frac{1}{4}$ lines long.

Iodine at this period violets in several lines from up the style to the base of the nipple.

This body is not so purely violetted as are the lines.

Appearance of a tubular neck to the nipple.

a. Calyculus of two layers.

b. Perianth.

c. Extent of the white dense tissue of the interior of the base of flower.

d. Nipple-shaped process.

e. Canal of style.

f. Green tissue of the base of the flower.

5. Double long section of base of flower bud $3\frac{1}{4}$ long.

Nipple evidently belongs to the white tissue of the base. Hypothesis, that the sacs are developed from the placental tissue lining the cavity of the interior.

The same figures have the same references.

Iodine at this period violets along the usual lines, which are adversely clavate, violetting not so pronounced as in 4.

6. Just before expansion of flower.

In this no trace whatever of the nipple was seen, all the dark colored part is homogeneous, and crowded with granules of amylum.

a. Calyculus of two layers.

b. Perianth.

c. Outer boundary of central white tissue, which at *e*, (*i*, *e*, the space inside *d*, *d*, two vascular bundles) is opaque from being crowded with amylaceous granules.

f, f, f. Three embryo sacs, having the same extensions as in *L. globosus*.

g. Canal of the style.

Twelve lines long appearance as if the bases of the styles canal was blocked up by a mammillar process, continuous with that part of the central tissue that is violetted by iodine.

7. Double long section of base of a flower-bud $3\frac{1}{4}$ lines long.

a. Calyculus.

b. Perianth.

c. Filament, which by its adhesion to the perianth causes the keeled appearance.

d. Central white tissue with its central nipple.

e. Canal of style, ending below in a triangular space occupied by the nipple.

Proper sequence of the sketches to be.

1—4—7—5—2—3—6

1 2 3 4 5 5a 6

The same Pl. DCXXIII. Fig. I.

1. Double long section of ovarium after fall of perianth and style from the cicatrix of which filaments are seen to project.
 - a. White tissue of centre.
 - b. 3 embryo sacs.
 - c. Young albuminous growth from one of those.
 - d. Another ditto much less advanced.
 - e. Convoluted funicle embryo.
 - f. Embryo.
 - g. Vascular supplies.
- 1 b. Represents *no. c.* of the same, but the filaments were not seen to traverse the albumen, at *a* is the end of the embryo sac? at which the tubes emerge, their cells are of large diameter and lax, at *b* another funicle adhered to this, forming with this the embryo.
- 1 a. Represents *d* of 1. The young albumen is 4-angular from pressure, each cell is crowded with grume and contains a grumous nucleus, this did not reach much more than $\frac{1}{2}$ down the cavity of ovarium. There was a tendency to grumous aggregation towards the bottom of the cellular part of the sac, *a* is the termination of the sac reaching to the apex of which are two tubes, which pressure did not shew in the albumen.
2. From another less advanced ovarium the sac was nearly cellular throughout the lower $\frac{2}{3}$, lowest cells being most developed, and the upper ones with faint walls and no nucleus, the tubes are enclosed *throughout*, but the sac ceased to be cellular.

The same Pl. DCXXIII. Fig. II.

Represents the united embryo of the same.

The inner tubes remain two, either to the end of the irregular edged sheath or near it, where this ceases they ap-

pear as three, they continue to do so till they unite and perhaps even after this. The cells of the sac are most developed, about the middle of the cellular part, they are not formed from the inner surface of the wall itself, but between this and the inner tubes, no nuclei were visible.

Above the cellular part of the perfect sac, are nucellar aggregations and in the same there is alike tendency below, no cells developed in the sheath.

The inner tubes are articulate towards the apex of the cellular part, and probably also once or twice in this part.

The same Pl. DCXXI. Fig. I.

1. Double long section after the fall of the corolla and style, no fecundation having taken place shews that the sacs reach to the bottom of the central dense tissue.

1 *a.* Upper part of sac of same 1-10.

1 *a.* Lower ditto.

b. Upper part of ditto 1-250.

2. Sac from an ovarium after fall, no fecundation, these sacs had become inflated, their lines of direction being conspicuous, they reach to the bottom of the central tissue.

3. Is the lower portion of sac, about the same period shewing a tendency to independent cellularity.

4. Double long section after the fall, fecundation has occurred, as is evident from the boyaux protruding from cicatrix of style.

4 *a.* Represents the lower part of fecundated ovulum of the same, the left hand one, at *a*, is the termination of the sac.

The same Pl. DCXXI. Fig. II.

Long double section of *L. leucosiphon* just after the fall of the corolla and style.

The lower $\frac{1}{2}$ of ovarium presents a large sub-irregular cavi-

ty occupied by the embryos, and their contorted funicles, of the four, 2 are united into one, 2 remain separate.

2. Represents an entire (independent) sac, embryo and funicle. The sac towards the cellular part contained much grumous matter, above it was nearly empty, here and there were amylaceous granules. Each cell of the cellular part is crowded with grume and containing one nucleus.

In the upper part of the attenuated part a few cells without nuclei were present, but towards the terminatinn of the sheath which is at *a*, no cell had been developed.

Beyond this the continuing tubes were increased in size, the two first joints, presented 3, the terminal one several, at its apex was the commencement of the collet.

7. *Loranthus involucratus*.

Caule elongato lenticellato, plumbeo, fol. ovalia acuminata carnosae, subintegra venis subtus præsertim primaria secundarisque inferioribus rubescent, flores capitati. C. breviterpedunculati axillares nec ne etiam infra axillares, involucro 4-phylo cincte.

Foliola involucri lanceolata plus minus rubro-colorata pubescentia brevissime velutina. Pedicelli brevissimi his oppositi et adnati, pubescenti.

Calyx dense pubescente tomentosus 5-dentat.

Corolla tubulosa, extus pubescens in laciniis 5 spathulatis reflexis partita, viridescens laciniis castaneo-rubris.

Antheræ erectæ adnatæ filamentis tubum corollæ paullo excedentibus, coccineæ. Stigma capitat. coccineum, antheras paullo superans.

Ovarium ut in ordine, ante fecundat. ex ovulatum.

Capitula aggregato numero vario, cujusque evolutio etiam varia.

HAB. Assam. Versus Kuchabat : *March 5th*, 1836.

This species certainly corroborates Mr. Brown's idea of the affinity of Loranthaceæ with Proteaceæ, an opinion which is

borne out by several facts, I should consider this an approach to *Lambertia*.

An *L. involucratus* Roxb. Fl. Ind. (ed. 1832,) 2, 188.

MODECOPSIS.

Modecopsis vaga, Pl. DCXXVIII.

Calycis parietis omnino adnata pericarpio demum baccata, viridescens, secus lineam junctionis cum pericarpio rubescens.

Pericarp. vel epicarp. carnosum-corneum ambitu azurescens cæterum albidum.

Mesocarpium fere osseum, pallide brunescens, intus endocarpio albo subspongioso hinc elline fissum vestitum. Semen unicum maximum ovatum pendulum inferne acutum supra latius, obtusumque. Tegumentum hinc adhærens nullum, an ideo endocarp. spongioso-cellulosum ad testam referendum.

Semen carnosum densam distinctione partium nulla, nisi forsitan radiculae, (cui forme umbonis depressa a quo affixum est semen) medio basi usque ad media linea lutescente pilosa cellulosa notatum.

Calyx demum e pericarpio secedens, bivalvis, valvis reflexis interdum bipartitis.

HAB. In sylvis Noadwar examinavi semina? tantum, *Feb. 17th*, 1836.

Habitus omnino Modecca, calyx recessus ultimo in lacinis lobosve 5, sepalis respondentibus fissus.

VISCUM.

1. *Viscum aphyllum*, Pl. DCXXX.

Caulis basi simplex, subrotundus, tunc rotundato anceps, ramis complanatis tetragono-ancipitibus, ramulis complanatis sub 5-striatis, stria media majora.

Length and proportions are very variable.

Floribus monoicis sessilibus ad articulos sæpius ternis sæpiusque fæminea, unica centrali duobus lateralibus (scrotnis) masculis.

Bractea cupuliformis ore emarginat. ovarii tubum ovatum $\frac{1}{2}$ recondit.

Flos fæ: minutus tubo ovato perianthio suberecto, sepalis cordatis.

Stylus sub 0, stigma magnum discoideo-convexum.

Saculus embryon. 1, ante fecundation: imperforat. simplex.

Bacca pisiformis lutescens glabra, demum albida, basin bractea persist. suffult.

Semen erectum visco obtectum, pericarpium obcordato-oblongam compressam cornubus maturis obsoletis, virida basi lineis venoideis albis (pericarp. ven.) albumen $\frac{1}{2}$ nudum virida.

Embryo periphericus, infra medium, radicle pointed out by a greener spot, on one of the compressed edges.

Fl. masculi sæpius ut videtur 3, sepalis-sepalis erecto-patentibus apice reflexis, bracteatis ut fæmine.

Plant of a lively yellow green.

The branches become rounded by age, but the joints are

always swollen, still the aneups edge is always traceable, the branchlets are slightly spiral twisted, the direction of the broad and narrow faces of the joints alternates.

The perfect females are much more numerous at a given time, than the males, fecundation is very common.

The real state of the inflorescence is a ternary flowered spike, but often on either side of a solitary, (terminal female) there is a female and two males, or there are 3 ternary spikes aggregated. The females are by no means always central, particularly in the central spike of a thrice ternary one.

The phenomena are as in *Viscum papulosum*, it is vain to attempt to determine the species by books, the characters given entirely omitting the seed.

Pl. DCXXX. Fig. 15, represents the parasitism of the specimen, which is a simple conical graft, without intermixture of any system.

The two barks adhered slightly, there is no pith in the parasite, probably from exertion, or where does the pith begin.

Pl. DCXXX.

1. Plant natural size, joints rather too broad.
2. Portion of a branch slightly magnified.
3. A flower-bearing joint.
4. Double transverse section of anther.
5. Pollen (in water.)
6. Female flower with the two males developing laterally.
7. The same, two sepals removed.
8. Double long section of ovarium of same period, *a* the the embryo sac visible in its axis.
- 8*a*. Embryo sac detached.
9. Embryo sac after fecundation, M. $\frac{1}{25}$, a pollinia visicle.
- 9*a*. Do. $\frac{1}{50}$, the apex of the sac with a distinct interruption of continuity.
10. Young fruit about $\frac{1}{3}$ advanced.

11. Ripe fruit.
12. Long section to expose the seed.
13. Seed detached, the vein-like marks are what I take to be the remains of the true pericarp, or endocarp, which in fig. 10, are seen to extend above the young seed.
14. Long section of seed, through its large diameter, the appearance of a tegument is due I think to a peculiar disposition of the superficial cells of the albumen, which is, except towards its base, naked.

HAB. Malacca.

2. *Viscum* sp. Pl. DCXXXII.

1. Male flower before expansion.
2. Do. after expansion.
3. Do. sepals partly removed.
4. Anther and its sepal.
5. Front view of stamen.
6. Back view of do.
7. Lateral do.
8. Section of anther (unsatisfactory.)
9. Apex of branch with two female flowers.
10. Long section of female flower before expansion, no cavity visible in the ovary.
11. Do. more advanced, cavity visible and occupied by the embryonary sac.
- 11a. Embryonary sac enlarged.
- 12, 12a. Similar sections, but taken at a more advanced stage. The tissue immediately around the sac is lax transparent, *a* represents the commencement of that which subsequently becomes the coriaceous tegument, *b* of the viscous tissue.
13. Female flower after the fall of the perianth.
- 13a. Section of do., the same letters have the same references.
- 13b. Embryonary sac now rendered opaque by albumen.
14. Long section at a more advanced period, letters refer as before.

15. Do. more advanced.

17. Same more advanced. Embryo just commenced.

18. A good deal more advanced.

HAB. Tongsa iu Bootan.

Viscum, monoicum Pl. DCXXXI.

Bacca pisiformibus circa apicem areoli cicatricis sepalorum, imo apice reliquias styli et stigmat gerent, in pedicello brevi robusto basi l-bracteato, fere læve. Accedit. materies crassa gelatinosa dehiscens.

Viscum tenuissimum hyalinum circa semen.

Semen subobcordatum compressum erectum viride basi album. e qua ascendunt. filii (venæ?) albæ incompleti, one of them hinc utrinque apicem versus in sitam product. One of the smaller sides hinc, mammilla pointing out the apex of root notat.

Albumen copiosum carnosum viride. Embryo transversus leviter curvatus. Radicula longissima peripherius. Cotyledones incumbentes carnosæ foliaceæ discretæ.

The white vein-like threads are the remains of the true pericarp, which in other species is much more developed, complete and persistent. It is difficult to ascertain the situation of the faces of the seed as it is so easily disturbed by pressure.

Attachment simple, plant pendulo glabra ramulis (et folia) oppositis flexuosis sulcato-angulatis.

Fol. opposita basi in petiolo brevissima attenuata ovato vel lanceolato-oblonga inæquilateral sæpe falcata e subundulata concava basi 3-venia, venis supra prominulis obtusa coriacea, brittle.

Flores minuti in glomerulis axillarib. inserti, sæpius e ternis, aliquando e binis, aggregat.

Masculi et fæminei in eodem glomerulo, fæm. ut plurim. numerosiores.

Flores basi bracteæ cupuliform. bidentato cinti vel solitarii

(ob abortu) vel uno duove laterali scrotino sæpius masculis ovarium ovato-globosum post laps. sepal. apice areolat. Sepala dentiforme æstiv. valvata.

Stylus conicus, stigma capitatum. Fructus, juniores pyri-formes papulosis maturi læviusculi papulis in carne quasi immersis punctulatis pisiformibus.

The gelatinous stuff is of late development, when the seed is half developed it will be found enclosed in gelatinous viscum, which has much the appearance of the mature gelatine. But when almost ripe, the seed will be found slightly surrounded with viscum, and almost in opposition with the epicarpium as it may be called.

Fl. masc. alabastro subrotundatus, ad medium usque 4-fida, sepalis fæmin conformibus.

Anth. 4, sepalis opposit. his insertæ, oblongæ anterior face with a number of alveola bearing white pollen.

It agrees tolerably well with character of *V. falcatum*, but there is no judging from mere habit and inflorescence, the fruit of this is so peculiar as to constitute the plant a subgenus.

V. monoicum ramis (foliisque) oppositis glabris sulcato-angulatis, fol. subsessilibus oblongis sæpe falcatis inæquilater basi 3-junioribus 5-veniis venis subtus indistinctis, coriaceo brittle, obtusis.

Glomerulis axillaribus, densifloris, floribus sessilibus basi bracteatis circumcinctis, solitariis binatis vel ternatis.

The inflorescence is excessively compound, the bilobed bractea represents the bracteola of a trichotomous triflorous, peduncle, as it often is, the evolution of the flower is very anisochronis.

1. Plant natural size.
2. Male flower bud.
3. Male flower, cut through longitudinally, 1 sepal removed.
4. Sepal and anther.
5. Transverse section of bud of male.

6. Transverse do. of anther after dehiscence.
- 7, 8. Pollen.
9. Female flowers.
- 9a. Ripe fruit.
10. Same cut away to shew the seed.
11. Long section of fruit (not ripe.)
12. Do. same more advanced.
- 13, 13, 13. Different views of seed, and endocarp.
14. Long section of seed not quite mature.
15. Do. of mature seed.

SCHÆPFIA.

Schæpfia sp. Pl. DCXXIX.

Arbor. mediocris, ramulis subnutantibus elongatis rubro-tinctis sæpe fasciculatis vel aggregatis. Foliis alternis exstipulat. Petiolis brevibus dilatatis $\frac{1}{2}$ tortis lamina lanceolata vel lanceolato-ovata acuminata integra tenera carnosiuscule basi subtrivenia venis secundariis distinctis arcuatis, cæteris reticulatis.

Spicis axillaribus, solitariis pendulis folia æquantibus ves excedentibus plurifloris, compressis, bracteis minutissimis squamiformib. Flores cream-colored, tinged with purple fragrant.

Perianth. superum, cylindraceum 4-5 partit. laciniis æstivatione valvatis demum revolutis margine minute puberulis.

Stam. 5, sepalis opposita, laciniar. basibus inserta. Filament. (liber) breviss. filiforma. Anth. biloculares, terminates, longitud. dehiscent. Pollen album glaberrimum subtrigonum, triplicat.

Ovarium inferum omnino, apicem versus annulatum situ insertionis. Perianthium disco magno carnosio integro luteo-coronat. subangulata.

Stylus filiformis, stigmato ovato 3-revoluta papillosa inclusa. Ov. apice unilocularis, inferne trilocular, loculis 1-ovulatis.

Placenta apice libera conica ovula ferens, ovula ad nuclei redacta, extus convexa intus plana, mere cellulosa, et omnino simplicia, fasciculus pilor. simplicium alborum, pone stamen quodque.

Tubus perianth gibberibus totidem obsoletis quot laciniis et his alternantibus.

This is I believe Schæpfia.

It is a very curious genus, evidently uniting Olacineæ, Santalaceæ and Loranthaceæ, but more akin to the former than to either of the others.

Obs. The calyx is reduced to a mere ring and is evidently the transition from that of Loranthaceæ.

With Santalaceæ it agrees, in opposition of the stamina, the valvation of the perianth, the structure of the placenta and in the ovula, which are reduced to the nucleus.

With Olacineæ in habit, structure of the ovarium, and valvation of corolla.

With Loranthaceæ in the valvate perianth, opposition of stamens and in the inferior calyx.

It is curious that in these orders, in which the calyx is rudimentary, the corolla is much developed, and vice versa, of which Santalaceæ are a notable example.

1. Alabast just before expansion.
2. Flower.
3. Do. vertically.
4. Corolla longit. spread open.
5. One of its laciniae, stamen deflexed shewing the fascicle of hairs.
6. Back view of stamen, 6a inner or front do., 6b lateral do.
7. Pollen. 7a do. immersed in water.
8. Hair from the fascicles behind the stamina.
9. Pistillum.
10. Stigmata and upper part of style.
11. Ovary transverse section below the middle, 11a do. towards the apex.

12. Do. longit section.
13. Do. so as to shew the peculiarity of the placenta, and the cells in which the lower parts of the ovula are contained.
14. Ovulum, inner face of. 14a same viewed laterally.
15. Apex of the ovulum shewing it to be simple and hence nucleary.

HAB. Bootan Itinerary Notes, p. no. 876.

GRANATEÆ.

PUNICA.

Remarks on Pl. DCXXXIV.

Punica was I believe first separated from Myrtaceæ by Don, whose views have been adopted by D C., subsequently Mr. Lindley replaced it among Myrtaceæ, and has given a new and ingenious theory as to the structure of the fruit, which he supposes to be formed of many carpella, placed in two rows instead of one, the other irregularities being due to adhesion of the placenta with the bark and front of the cells. It may in the first place be doubted whether the mere fact of plurality of carpella would not be sufficient to indicate Punica to be distinct from Myrtaceæ in all Indian species of which the ovaria is bicarpellary. There can be no doubt that Lindley is right in asserting that Punica has a plurality of carpella, but I am disposed to doubt the fact of their being arranged in two rows.

The plurality of composition is indicated inter alia by the number of vascular fascicles of the style, as well as by the sinuosities visible in the upper portion of the stigmatic canal, to which the fascicles are always opposed, which sinuosities always correspond to the number of stigmata, with this number, which varies from 5 to 8, the cells of the ovarium,

as seen on a transverse section carried through the upper portion have a marked correspondence, and in cases where one is deficient, one of the septa is much increased in size, indicating it may be fairly inferred an obliteration of the cavity, the number agreeing with the upper tier of cells. It seems to follow, owing to the greater permanence of the style or stigma than of the ovarial cavity itself, that no other carpella enter into the formation of the fruit, and hence the idea of an inner or lower series is untenable. Of the greater permanence of the styles or stigmata over the cavity of the carpellary leaf itself ample proofs exist in *Compositæ Gramineæ Plumbagineæ*, and *Cupuliferæ*?

It need not therefore be insisted on, it may be sufficient to state, that if Mr. Lindley's view be correct, there must be the same number of stigmata as there are cells. This I do not find to be the case, my idea is this. The ovarium is formed of from 5 to 8 cells, which towards the base of the fruit become much distorted by various growths of the placenta, and it is possible that a sort of dislocation adds to the confusion, that the number of cells can only be ascertained by a transverse section carried through the upper portion of the ovarium.

The placenta are various in the situation of the upper cells, they are always parietal, of the lower both axile, fundamental and parietal. It is a general rule that towards its apex the pistilla when compound has a tendency to revert to its utmost possible simplicity of structure.

The situation of the placenta of the upper cells is alone, a great objection to Mr. Lindley's view, since the placental suture would, allowing it to be true, be turned away from, and not towards the axis, an anomaly quite unheard of.

In my view the irregularity is due to cohesion, and is not opposed to any well known law.

In very young ovaria before the appearance of the ovula, the cells are distinctly marked out, and they are evidently

visible at a somewhat later period, when the ovula have just commenced to appear.

The affinities remain to be pointed out. These are most marked with *Soneratia* and with *Leptospartion Lagerstroemia grandiflora* of Roxburgh. These three genera form a group uniting *Lytharieæ* with *Myrtaceæ*, which group is at once known by its valvate calyx. They all agree in this, in the structure of the petals, and ovaria, and in habit.

They differ from *Myrtaceæ* in almost every point, but the adhesion of the calyx with the ovarium.

No pellucid dots exist in *Punica*, neither are there any traces of their existence, the pellucid portions which do exist are not of a glandular nature, and appear to depend on obliteration of green parenchyma taking place irregularly, I find however that in many instances, pellucid markings do exist, but they are unaccompanied with any aroma. There is a tendency towards an intramarginal vein, but to this I attach little importance.

In habit and especially in the shortness of the branchlets, there is much analogy with *Pomaceæ*, as likewise in the tendency to become spinous. Compare this with *Mespilus japonia*.

With *Lythariea* they have most points in common agreeing with them, especially in the valvation of the calyx, the structure of the petals and ovula, differing essentially in the union of the calyx with the ovarium, or in the inferior fruit.

With *Myrtacea* they agree in opposite leaves without stipulæ, in the inferior fruit, differing in the valvation of the calyx, the nature of the petals, stamina, and plura carpellisation of the ovarium.

Punica agrees with *Memecylon* in the convolute cotyledons, and among *Lytharieæ* above all others with *Grislea*, the coloration of the flowers being in both the same, and so far as the calyx is concerned of an unusual nature.

What I have said about the greater permanence of the stigmata over the lamina of the carpellary leaf is on

reconsideration untenable, because the stigmata being in my opinion obviously continuations of the placentiferous margins of a carpellary leaf, it cannot subsist without the other. Besides the two fascicles of vessels of composite ovaria prove, that its formation is binary, and hence in Polygoneæ and Plumbagineæ, there should be an equivalent number.

It may fairly be stated, that the least permanent part of an ovarial leaf is the inflected margins. This subject is ill understood and can only be cleared up by extensive examination of very young ovaria. I think I have observed in *Naias*, that the ovarium is formed after the ovulum, for in a very early period, the papilla of this will be found $\frac{1}{2}$ enclosed and surrounded by two scales the coalition of which forms the ovarium.

The situation of the stamina in *Punica* is unusual and suggests curious reflections. Something like it occurs in *Barclaya*. The usual situation of stamina is above the petals or at any rate nearly on the same plane, and in those cases in which the stamina are indefinite the inner ones are generally above the outer. In *Punica* the reverse is the case, the outer are indeed on the same plane as the petals, but the rest are below these, and the innermost are so in an unprecedented degree. It is curious that such an arrangement does not occur in those cases of perigynism in which the ovary is entirely free, and the tube of the calyx is lined with a glandular lining of which the stamina are evidently the continuation.

The obliteration of various parts of vegetable tissues is well worthy of study, it is the exposition of such that will settle the question whether in inferior flowers, the ovary is united to the calyx or to an excavated torus, (*Rosa etc.*).

The inferiority of a fruit is as capable of being explained by one supposition as by the other, but if obliteration be a rare phenomenon in vegetables, we shall be authorised in adopting the latter, since the existence of the different lay-

ers that otherwise should exist, seems to be by no means frequent.

Two layers ought to exist at any rate, if the inferiority be ascribable to adhesion of the calyx with the ovary, the outer would be referrible to the calyx, the inner to the torus, from which the petals and stamina are growths.

The instance Punica is precisely the reverse of that of Nelumbium, in which there is such an enormous growth of disc, without the production of any stamina above the general level.

Pl. DCXXXIV.

1. Calyx before opening shewing its valvation, 1a do. vertical view.
2. Flower, 2a do. long section.
3. Stamen before maturing, inner view, 3a do. outer or back view.
4. Perfect stamen front, a back, b lateral, the anthers are curious, and differ from most others in the nearly globular connectivum.
5. Pollen, 5a do. immersed.
6. Stigma viewed from underneath and vertically, the lobes seen on the face of the stigmatic canal a are opposite to the carpella, each has a vascular fascicle, and each becomes a stigma, although this cannot be demonstrated in the state of maturity.
7. Transverse section of style, shewing that it has several vascular fascicles, each of which belongs to a distinct carpellum.
8. Stigma of a very young bud.
9. Ovary transverse section of, near the base, where all regularity has ceased.
- 9a. The same towards the apex, the number of cells generally correspond to the number of stigmata.
10. Ovula, 10a do. longit section.

11. Longit section of bud $1\frac{1}{2}$ lines long, calyx well developed. Petals squamiform, evascular. Anthers nearly sessile, ovuliform. Stigmata distinct and separable.
- 11a. Petal. 11b. Stamina. 11c. transverse of ovary, white triangular spots represent the placentæ.
12. Transverse of ovary a little more advanced, still no regularity, *a* placentæ, *b* septa, *c* spaces afterwards occupied by ovula.
13. From an alabastrum $2\frac{1}{2}$ lines long, *a* placenta portion of young ovula, *b* stamen, *c* the same submitted to pressure contains nothing but the grumous formative mass which appears marked out.
14. Alabast. $4\frac{1}{2}$ lines long, *a* stamen, *b* do. subjected to pressure, outlines of formative mass visible and this is separable by pressure, *c* grumous formative mass, *d* ovulum much enlarged, but with no annuli.
15. Bud $6\frac{1}{2}$ lines long, a long section of anther one cell empty, the other filled with the grumous mass, *b* portion of this $\frac{1}{20}$ cells towards the peripheris commencing to be distinct, *c* ovule, it has already commenced to turn on its axis, the annuli are distinct, *d* same under pressure shewing that there is no distinction of coats as yet.
16. Bud, $8-8\frac{1}{2}$ lines long, *a* portion of formative mass, cells now distinct and easily separable. They are curiously marked and occasionally look as if ternarily divided, but this may arise from the development of the longitudinal folds, *b* two cells separated $\frac{1}{20}$ *c*, *c*, *c* ovula, *d* same submitted to pressure, shewing that the coats have been developed by the growth of the annuli.

The actual period of separation of the cells of pollen from the parent cell remains to be proved or rather shewn.

In conclusion the structure of the ovaria of this genus is very curious, but is explainable on other grounds than those adopted by Dr. Lindley.

The base of the ovarium of this genus, (from which part ideas of true structure are alone to be deduced) is bilocular, the cells containing an indefinite number of ovula, which are attached both to the axis, and to the bases of the cells, as well as to the lowermost parts of their outer parietes. Thus far it does not depart from the character of the order, which is essentially completely bicarpellary. Above these two cells are arranged in a cruciate manner, four others, which are accupied by thick parietal placentæ, on which the ovula are arranged, these looking outwards. The above number however would not appear to be constant, but if the bottom be always bilocular it is quite enough.

The explanation I consider to be obvious and totally different from that given by Dr. Lindley. For we have first in the bottom ovary the normal dicarpellary structure, and in addition a tendency in excess? towards parietal placentation, and the anomalies of the ovary arise first from the continuing inwards of the parietal placentæ to the axis, which part is also ovuliferous at the base, and second from growths inwards to the axis from the inner face of the ovary, by which the spurious cells are produced.

In favour of this view *Apteuxis* is to be adduced, a *Melastomaceous* genus in which the ovary is four celled, and the ovula attached to the outer walls of the lower half of each cell, and *Careya*, in which the placentæ are parietal. And in addition the structure of the stigma and style, which is obviously dicarpellary.

Lindley's view is wrong, because in all cases there is a correspondence between the number of styles and the cells of the fruit, when such arise from different carpella. The styles and stigmata being more permanent organs than the ovary! as in *Compositæ* *Gramineæ* etc. And because according to this view the placental sutures of each carpellum are not situated next the axis. The instance cited by Lindley of the permanent variety of apple is decisive of

the former law, and completely destroys his idea, unless it can be proved that the style is composed of more than two.

This genus is I think clearly not referable to Myrtaceæ; with which order it does not at all agree in habit: in which it resembles much more certain Pomaceæ, as well as in the colour of its flowers, particularly if attention to its short lateral branches, with respect to the assertion that *Punica* has distinct traces of pellucid dots in its leaves, it must be urged that as there is no tendency towards aroma in the plant, so there is no reason why they should be supposed to exist, and in addition the apparent traces that may perhaps exist do not agree in nature with these reservoirs, but are rather attributable to the suppression of green Parenchyma here and there, a circumstance of sufficiently common occurrence.

As to its proper station, I am by no means determined, probably it should be placed between Melastomaceæ, Lythrarieæ, and Myrtaceæ, with this latter it has affinity with *Soneratia*, if *Soneratia* belongs to the order, with Lythrarieæ through *Lagerstroemia grandiflora* and *Grislea*, with Melastomaceæ through *Memecylon*.

With Pomaceæ in habit, venation, and anthers, and granting Lindley's views to be correct in carpellation.

Examine, style its vasc. fascicles correspondence of upper cells with those of the lower, &c.

MYRTACEÆ.

TRISTANEA.

Stigma maximum patenta fungiforme, æstivat. staminibus supra inflexis equitans superficies superior rugosule medium infra 4, 5 locales margine tantum stigmatico e partibus 4-sepalis oppositis uniloculare vel basi loculis tot quot septis apice conico ductu stigmatis tantum forato.

Ovula 00 oblonga sub acinaciformia, foramine hilum versus tegument bina interiis tenue. Pl. DCXXXVI. Fig. IV.

Odor alabastr apertor fragrant.

This plant differs from the other *Sonneratiæ* in being apetalus, and in the maximum dilatation of the stigma, and perhaps in the structure of the seed.

Both it and *Sonneratiæ veræ* have a peculiar aspect dependent upon the stomata being present on both sides of the leaves, but in *Duabanga*, they are confined to the lower side.

On what account the genus was placed among *Myrtaceæ* is difficult to conceive, that order being extremely well defined, and presenting no approach to such a structure of the calyx, and freedom of ovary.

If *Sonneratia* belongs to any order hitherto characterised, it is to *Lythrarieæ*, and I am at present inclined to place it there. In this case the section will come near *Lagerstroemia*.

Fabricia can scarcely be *Myrtaceous*.

The continuation of the ovary with the central system, the origin of the disc. or torus and the continuation of the

calyx with the external system is very distinct in this plant. The torus is evidently limited to the space between the inner vessels of the calyx and the wall of the ovarium.

Fabricia Fætidia, *Sonneratia*, *Duabanga*, *Rhizophoræ*, *Carallia*, *Lythrarieæ* etc.

The group formed by the valvato-epigynous orders is almost as defined as those of the hypogynous orders.

2. *Sonneratia acida*.

Arbor. humilis, ramulis pedicellisque articulata. 4-gonis fol. obovato-oblongis carnosis, integris marginibus cartilagineis secundariis subdistinctis floribus terminalibus solitariis binisve in pedicellis articulatis, articulatis magnis conspicuis. Calyce 6-partito.

Embryo conferrumin. superfice sulcis parum profundis exarat. squamulis ut videtur nullis.

The original axis of ovarium is in *B. racemos*, pushed to one side, laying close to the inner wall of endocarp, and is to be easily mistaken for a linear raphe-like placenta from the apex of which the seed hangs, about the apex of the seed, as in that species the abortive ovula are to be found.

Systema centrale subovutum indistinct.

The seed of *Barringtonia* is sufficiently remarkable, I imagine the central part represents above, the radicle; below, the plumule, and I also imagine that all the parts between the lowest scales of the superficies and the radicle is adherent cotyledon, or is it an instance of an immense radicle, and two or several minute cotyledons (represented by scales and an inconspicuous plumula.)

To this, which is suggested by the radicular central system being internal, not reaching the superficies, there is a great objection in the irregularity in number and situation of the scales. The internality may arise from the cotyledons being produced into basilar auricula concealing and enclosing the root, as occasionally happens.

The development only will clear up the point, for even if

the scales become enlarged foliaceous during germination, they will not, I think necessarily become plumularily, some cotyledons during germination becoming decidedly leafy.

On the whole, this peculiar embryo appears to me distinctly analogous to that of *Dracontium* and in a less degree to that of *Cryptocoryne*.

The leaves are distinguished from those of *B. racemosa* by the cordate or even bi-auriculare base, and by the consequent less spatulation.

Can this be *B. alata* Wall. Cat. e Moulmein.

Species distinct, fruticosa, racemis erectis paucifloris, loculis ovarium uniovulatis, calyce basi gibberibus. Fructibus conoideis, basi alis carinisve amplis (gibberibus ampliat.)

RHIZOPHORACEÆ.

RHIZOPHORA.

General Remarks.

In this tribe the radicle is developed before it reaches the ground, it passes out at the apex of the ovary. The edges of the opening becoming brown and ragged. The exerted part of the radicle is green, it is at first subulated but after it has reached some length, its greatest diameter is

at about $\frac{1}{2}$ from the apex. Towards the point the radicle becomes indurated and at the very apex, there is a brown callosous spot. The induration increases in extent as the root increases in length. The anatomy is simple, from the collet to the commencement of the induration, it is entirely cellular. It consists of a rather thick outer tunic or bark, and of a central cellular part. The cells of the central part are rather larger, but otherwise do not differ from those of the bark, they are lax and of a rounded form, and contain many amylaceous globules. In the roots which have reached an inconsiderable length, the cells are chiefly of a brown color, but this color disappears in a great measure afterwards. Among the brown cells, larger and more prominent ones are visible. The central part is thickest towards the collet. The bark is thickest at the thickest part of the root. The woody fibre is very dense and coheres very strongly together. It has no connexion with the collet, and reaches in a radicle of 5 or 6 inches in length to an inconsiderable distance, say 1 or $1\frac{1}{2}$ inches. The fibres do not occupy the whole of the substance except at the very apex. At a distance of $1\frac{1}{2}$ line from this part, the original cellular centre is still visible.

Queries, are there stomata? 2. Is the fibrous tissue originally connected with the collet, or is it formed in an ascending direction? 3. At what period is the whole of the radicle occupied by this tissue?

HAB. Mergue.

4. *R. parviflora*. Cotyledons ovatæ carnosæ plano-convexæ plumula conspicua intra cotyledons obcondit. materia lucida mucilaginos. nidulans.

In *R. candilaria* and *R. macrorhiza*. They are fleshy, coriaceous and consolidated, the plumula is very conspicuous and large received into the prolongation of the cotyledon, which

* See a paper in the Transactions of the Med. and Phys. Society of Calcutta, 1835.

is of the same appearance as the radicle and articulation with it at the base of the plumule.

The cotyledons are more or less conical from the middle upwards.

In *R. decandra* they are broadest at the base or upwards. The fungous substance which surrounds the base of the cotyledons of these 3 species appears to originate from the coats of the ovulum, which at a subsequent period become detached and pushed towards the bottom of the pericarpial cavity. In these three species the apex of the ripe ovary, is exserted, in other words, it is only $\frac{1}{2}$ inferior, coupled with this, we have cotyledons of a peculiar form and consolidated, and the bases of which are naked.

HAB. Malacca. In littoribus limosis, Pulo Bissar.

Differs from *R. conjugata* in its smaller stature, length of style, and smaller radicles, more villous petals, more elongated base of flower, etc.

The species are very difficult of discrimination, no characters can be drawn from the leaves.

1. Portion of a plant nat. size, except the fruit, which is not fully developed.
2. Bud, the sinuses have subprocesses, wherein another approach to *Lythariæ*.
- 3, 4, 5. Views of expanded flowers.
6. Partium situs et alternation.
7. Lateral of anthers, alternate with petals.
8. Oblique of anther opposed to petal, I am not sure whether the one is mucronate, the other is emucronate always.
9. Transverse of anther.
10. Calyx and pistillum, one lacinia of calyx removed.
11. Long section of pistillum, below the ovula is much lax filamento-cellular substance, a provision for the rapid growth of the embryo.
13. Ovulum.
14. Long section of do., I am not sure whether they have a second tegmen or not, if so, it is united to nucleus the cavity of which at this period is very distinct.

The ovarium of *Rhizophoræ*, is at an early period altogether superior, consisting of two fleshy scales with their margins rolled in; if mature it would be described as ovaria e folliculis 2 compositum.

The calyx then consists of 4 triangular thick coriaceous sepals, entirely enclosed in the connate bractes, the inner angle meeting in the axis; except at the base, it is at a later period, it becomes inferior.

The stamina appear as of the innermost locullus was much the smaller.

If the above sections be compared, it will be seen that the line of attachment of the ovula remains throughout nearly the same, and that the principal changes consist in the elongation of the so called tube of the calyx which is obviously nothing but pedicel.

In *R. conjugata* the slight inferiority of the cells, if at all is perhaps more evident. In both what is sufficiently remarkable the epigynous or rather hypogynous disk is an evident extension of the ovaria tissues.

In both the appearances of inferiority are heightened by the disappearance of the lax tissue of the apex of the pedicel, by which a cavity for the most part inferior may be obviously formed.

Another circumstance, to be borne in mind, is the precise line of discretion of the sepals, for the two do not correspond, if this be taken from the outer edge, the cells are not inferior at all, if from the inner they are slightly.

The phenomena are included in an elongation of the pedicel, by which the calyx appears furnished with a tube, and by the development of a glandular disc from around the base of the ovary, by which the petals and stamens are elevated above the original common line of attachment.

In this instance there is nothing to warrant the adhesion of the calyx to the ovarium, the parts always maintaining their original correspondence.

(*Candelaria*.) *Rhizophora*.

Arbuscula foliis ovatis mucrona sphacelato terminatis, coriaceo carnosius subtus brunneo punctulatis, venis secund, distinctioribus. Pedunculis axillaribus bifloris, petiolis 3 plo brevioribus, floribus 12 andris, fructibus subulato clavatis, sublaevibus nutantibus.

These two species are with respect to foliage very similar.

The trunks of both are supra terraneous. The first is a low tree, the second has scarcely any trunk, being a mere crown, the base of which reaches the high water mark.

In *R. odorata*, the petals only embrace during æstivation their respective stamens, they are white fleshy and sweet smelling. The structure of the anthers is very remarkable the connective is fleshy and large, the pollen is lodged in cavities arranged closely along its flattened sides and right and left with regard to the axis, these cavities or sacs have no mutual communication, the cuticle of the connection at any early period entirely continues with the substance, a short time before expansion separates along the flattened sides into unequal valves, the inner of which becomes entirely free from its original connection, except at its base, the outer by far the larger remaining attached by its apex and base. The connection is thus exposed, it presents a locular appearance, the areoli corresponding to the originally closed sacs. The inner valves at a more advanced period incline inwards over the style and stigma. The same organisation occurs in *R. Mangle*.

The direction of future separation of the valves is indicated by a faint linear depression. Both these species have the same structure of roots, *i. e.* soft and exceedingly fine woody fibre, imbedded in lax amylaceous cellular tissue. The bark contains in abundance hard roundish bodies, lodged in cavities of the nature of which I am quite ignorant.

6. *Carallia densiflora*.

Arbor. humilis ramulis compressis fol. breve petiolat. ovatis oblongo-ovatisve crenulatis coriaceis, longitud. latitudinem duplo superante.

Cymis axillaribus oppositis dichotomis folio brevior capitellatis, densifloris floribus inconspicuis viridi, albis, odora forte ingrato.

Cal. tubo brevi ad medium usque bipartit. laciniis lanceolatis acutis, persistent æstivat. valvatis,

Pet 6-7 ovata, inciso-sinuata, sinubus calycinis inserta, quoque stamen oppositum æstivat. fovens. Stam. petalor. numero duplo, libera perigyna filam. crassa subulata, tubo calycina ad medium fere ejusdem parietibus accreta papillosa. Anth. bilocul. longit. dehiscent. versatilis. Pollen oblonga discus perigynus elevatus crenulatus crassus ovaria basin cingens.

Stylus filiformis, stigma capitat. 4-lobum, lobis rotundis cruciatis. Ovar. semi inferne nempe basi disco perigyno accretet, 4 locul., 2 ovulatis, ovulis pendulis, dispositione introrsum obliquis, foramen superne hilum prope ovul. integument. ovula per distincte, stipulis uncialib. caducis.

HAB. In aquosis circa Mergui : Dec. 1834.

BRUIGUIERA.

Bruiguiera. 10-angulata, Gr.

Foliis ad apices ramor. confertis petiolis uncialibus laminis lanceolatis acuminatis integerrimis, one side with a longitudinal flattish depression, vena centrale distinct, secundariis arcuatis, subtus etiam indistinctis.

Gemmar. squamis 2-uncialibus subfoliaceis.

Alabastrum decurvatis.

Floribus axillaribus solitariis oppositis, ascendent vel $\frac{1}{2}$ nutant. Pet. 6-7 linea albus amplis $1\frac{1}{2}$ uncial pedicello tubo calyce duplo brevior.

Cal. tubus obconicus, 10-angulatus, angulis cum ochroleucus rubro tinctis laciniis trigono-subulatis, duplo longioribus, apice incurvis, alternis.

Petala castanea conduplicato, elastica semi aperient laciniis calycis paullo brevior margine breve villosa ad medium fere biloba, sinu longe setigero lobis infra apicem paullo 1-setigeris.

Stam. 2 in sinu cujusque petalo. Filament filiform alba glabra contorta. Anth. linear connect. basi breve.

Stylus subulatus. Stigma radiis 4-bicalcaret minutis, petala æquante.

Ovar. 9, 10 angulata.

Ovaria 1-loculare, placentis 4 ad centrum productis sed non unitis, intimo margine incrassato utrinque 1-ovuligero, ovula, 8 pendula.

The ovary is distinctly 1-celled at the base, all the ovula coming out together even from the pressure in cutting a transverse section, underneath the mass of ovula is a cruciately divided white cellulo filamentous looking substance.

This is the contrary of what usually happens with regard to septa of compound fruit, which are very commonly incomplete towards the apex, but never, so far as I know complete in the middle and incomplete at the base.

Evidently an undescribed species unless it is Loureirois *R. sex angula*.

2. *Bruiguiera parietosa*, Gr. Pl. DCXXXI. *B. eriopetala*.

Fructus patentes vel pendula, calycis tubus ampliatus, obconico-pyriform angulis obsoletis tot quot sepalis, usque alternant. Sepal. immulatis patente ascendentibus incurvat.

Tigellus exsertus $2\frac{1}{2}$ uncialis, sursum leviter curvatus, inæquilateral. apice constrictiusculo, viridis obsolete sub 6-gonus.

Collet. much constricted, cotyledones hæmisphæricæ spongioso cellulosa, contained in a thick coriaceous leathery tegument, attached above round the base are the remains dark brown of the abortive ovula.

Number of parts of flower uncertain 8 to 12, of ovary sometimes 3.

Plumula conspicua viridis.

1. Plant natural size.

2. Petal laterally from a bud.

3. Same after dehiscence.

Hinc infra media processum carnoso subdentiform pilosculum. Anth. adnatæ apice porosæ.

Pet. 4 æstivat. leviter convoluta lanceolata, reflexa margine fimbriato, sprinkled with yellow farina.

Stam. 8 æqualia, fertilia, connectivo rubro basi pilis albis paucis deflexis. Stylus leviter declinat. Stigma subcapitat. Ovar. inferum omnino 4-loculare placentis profunde reflexis, angulis intrant apice ovuliferis.

Ovula 00.

HAB. Malacca. In sylvis littoralibus, Taugoung cling in arenos.

ALANGIACEÆ.

MARLEA.

Marlea unilocularis.

Ramuli petioli foliaque subtus ferrugineo-tomentosa, the leaves much less and only at the veins.

Fol. alterna exstipulata ovalia vel obovato-ovalia breviter cuspidata, patentia undique, supra atroviridia lucida subtus reticulata venatio quodammodo Artocarpea, generally oblique 3-veined at bases.

Spiciæ abbreviatæ petiolis breviores axillares, pauciflora suberniformes, (flores trilbracteæ), præ fragrant ferrugineo-pubescent.

Cal. superus obconicus tubo 6-sulcato, sulci oppositi sinu-
ses, ad medium 6-partit. laciniis dentiform.

Pet. totidem alternantia valvata coriacea extus pubescentum e basi latiori lineares a medio reflexo patent.

Stam totidem calycinis dentibus opposit. filam. dilatate brevia ad medium versus dense barbato-villosa. Anth. adnat. linear bilocular.

Discus epigynus well developed crassus 5-lobus, lobis petalis opposit.

Stylus clavato columnaris pubescens four-striatus, apice subulatus, united with stigmatic lines confluent at apex (in really bifid, branches intus stigmatos agglutinata). Ovar. omnino infera 1-loculare. Ovule 1, ovulum pendulum anatropum raphe completa! exactly as in *M. begonifolia*.

The filaments adhere slightly to the petals, they are arched, broadest at middle, the upper hairs ascend the lower $\frac{1}{2}$ descend.

Fragrance delicious like *Pergularia*, the stigmatic canal has four angles, stylus basi alternatus.

Evidently *Marlea* or *Stylidium* or something very much like it.

The petals and stamina except in situation, put one in mind *Loranthaceæ*.

No difference between it and *Marlea* except the 1-celled ovarium, but as *M. begonifolia* ought to have 4 cells instead of two, this perhaps is not of much weight, minor differences exist in sulcate calyx, its more pronounced lobes, and the lobed epigynous disk, the habit is very distinct.

CORNACEÆ.

CORNUS.

Cornus, Pl. DCXXXIV. A. Fig II.

I doubt whether this order ought not to be placed in the neighbourhood of *Loranthaceæ*, *Olacineæ* and *Santalaceæ*, particularly as the nature of the perianth is nearly as obscure as it is the above mentioned orders. It is almost continuous with the structures from which the calyx is derived, its æstivation is valvular.

However the lobes of the stigmata are opposed to them, and this is a strong objection, because two organs in double series of the same denominations never are opposed. This at least holds good with regard to the calyx.

The hairs on the back of the petals are attached by the middle.

The ovary is certainly pluri-compound the normal number is pointed out by the lobes of the stigma, which are four,

and by the number of vascular fascicles of the style which are four on the axis of each lobe of the stigmatic canal.

The ovula are solitary, and curiously situated, they are transverse with regard to the ovary, although their conformation is entirely similar, the ordinary ovula having ordinary direction. The nucleary ends of both ovula point to the same direction.

HAMAMELIDEÆ.

OLACINEÆ.

OLAX.

Olaæ sphaerocarpa.

Caulis erectis angulato sulcat. fol. subdistincta oblongo--lanceolatis margine revolutis.

Floribus solitariis in axillis, albis pedicellis foliis multo brevioribus calyx annulus sub 3-denticulat. demum urceolatus.

Petala 3 in toro annuli more ovarium apice emarginat. basin cingens insert, $\frac{1}{2}$ erect, $\frac{1}{2}$ super patent, more crucifer. æsti-

vation viridescent valvate apicib. subintroflexis cum denticulis calyces alternant.

Stam. 3 petalis oppos. corum una in apices versus inserta introrsa bilocular. longit. dehiscent. filam. dilatat. brevia. Utrunque stipata sub staminodiis albis cellulosis, bipartitis extrorsus concavis stylus breviusculis. Stigma capitat. 3 lob. Ovar. superum, ovula e placentæ centralis apice conico pendula in loculis totidem receptis.

It is difficult to ascertain the venation exactly, but if the filaments are scraped off, each petal will be found to have two large vascular bundles, the intervenia being supplied by backward anastomosis. Hence it is probable that each is composed of 3 pieces, and this would explain well the situation of the staminoid and stamina or as the petals are simple emarginate it is also obvious that they may be composed of two, the fertile stamen alternating with them.

The stamina do not derive their vessels from those of the petals which is against the last hypothesis, on the contrary these petaline vessels exactly alternate with stamens.

There is something analogous to an articul. in the staminoidia, and the vessels of these are more distinct than those of the central part.

The ovula are certainly nucleary, at the time of flowering, one is fertilised, and this presents a curious membranous appearance along the side or edge next the placenta.

Stamina appear equally developed from an early period.

The ovula are worth examining, it would seem as if in the fertilised but abortive ones, the only ones I have seen there is a tube along the inner edge, and perhaps protruded from the apex. Fig. II. Pl. DCXXXIV.

Although Mr. Brown plainly shews, that the common mode of adhesion is in pairs, the want of correspondence of the petals, vascular fascicle (3 its excentricity) with the vessels of the sterile stamens must be borne in mind. The thing is easily settled by early observations or by examining the venation of those Olacineæ with the 5th petal free.

Olaæ loranthiformis, Gr.

AMPELIDEO.

Cissus.

Cissus spicifera, Gr.

Scandens cirrhifer.

Cirrhi oppositifolia.

Folia petiolat. (petioli utrinque incrassat.) læte ovalia vel ovato-cuspidata, basin versus excepta distanter serrata aspectu Menispermeo.

Racemi spiciformis, oppositifol. vel terminalis, solitaria, vel dichotoma pendula pedules, like tails, sulcate thickened at the base and looking like the ends of the petioles. Flores subsessiles, 3-5 aggregati, alabast ovalia.

Cal. minutissimus a mere rim irregularly toothed round apex of pedicel.

Petala 4 margine valvate, margine apices versus quasi in duplica oblonga concava patente reflexa.

Stam. totidem petal opposita. Filam. longa, petiolis paullo brevior apice constricta. Anth. subcordatæ bilocular sinu affixa longit. dehiscent.

Ovaria magnum, apice areolat. lateribus exaratis lineis 4 profundis in quibus filament nidulant bilocul. stylus sub 0. Stigma obtusum locul. biovulat.

The apex of the ovarium marked with 8 ovate or lanceolate impressions, ovula ascendentia anatropa (with two integument.)

Fructus disposed as the flowers, ovuli elliptic green, size of a small gooseberry baccate containing 2 oblong, plano convex erect seeds with a castaneous tegument, curiously intrant into fleshy albumen.

Embryo in the axis of the base of the albumen. Radicle longish subcompressed, inferior cotyledons, ovato-cordate with broad base, white flat foliaceous veined.

Fruit marked especially towards apex with black longit.

lines converging to summit. Pollen in water globular with inconspicuous pores, granular aspect.

So far as I can see although the difference in inflorescence is so remarkable, this scarcely differs from *Cissus*. It has no torus whatever. It is to be considered as a cymose spicate form.

EMBAMMA.

1. *Embamma heteranthum*, Gr.

Scandens.

Cirrhi gracilis setacea oppositifol. foliis longe petiolat. ternata, foliole anguste lanceolat. mucronato acuminat: distanter serrait, subtus pilis basi elevatis hirta, subtus albo tomentosa. Petiolis caulisque novellium ferrugineo-tomentos. lateral leaflets $\frac{1}{2}$ cordate at base outwardly.

Peduncles of frondose inflorescence cirrhigerous near the base, with the frond pinkish. The inflorescence is the same as that of *Embamma* similarly caudigerous, but flatter less lobed, along margins project, a few distant stout spoke-like stalks tomentose.

Immersed flowers, surrounded by an irregular edge (of the frond), 3-4 petals. Petals triangular cordate concave with subinflexed margins insertion narrow, twice as many, opposite anthers large cordate inserted in sinus, bilocul. longit. opening.

No style, stigma inconspicuum, ovary 2-celled, ovules 2 erect, collateral transversely broadest.

Apex of stalks of marginals dilated, into a cup-bearing petals and stamens as in those of disc.

Ovary same as in discoid but immersed, $\frac{1}{2}$ inferior, 2 ovules in each of the two cells ascending, style more prominent than in those of disc.

Hairs tomentum long. irregular spirally twisted. Raphides very numerous. Frond reticulately veined, veins

appearing to be anastomosing into a circle round each flower, the ovary supplied by branches from this ring.

The chances are against *Pterisanthes*, being really distinct.

The marginal flowers are exactly like the others, even to the rim from which the petals and stamens arise.

Embamma heteranthum, fol. ternatis, anguste lanceolatis subtus tomentosus floribus marginal pedicellatis.

HAB. Malacca. Verupha Aloor Golah. An approach to *Pterisanthes*.

2. *Embamma caudigerum*, Gr. Pl. DCXLVI.

Habitus omnino Cissi vel Vitis. Partes novellæ arachnoideæ lanata cirrhis oppositifol. fol. ternatis, ovato-lanceolatis distantes dentatis dentibus mucronigeris, subrepandis lateral lateri exterior obliquis basi subcordatis. Each serratures and point ends in a fleshy mucro.

Cirrhis florigeris oppositifoliis infra medium pedunculum sanguineo-rubra incrassat. pendulum exserent spadix alato-lobata, vel potius ex axi et alis 3 oblongo-triangularibus alternant tunc nudificatur. iterum apicem versus loba alii minores ambitu rotundato apice imo clavato incrass.

Flores imbedded in the dilated portions, generally on its surfaces, a few are marginal. The amorphous end of the cauda, also bears 2 or 3, they are arranged in oblique lines, those of the two surfaces do not correspond, they are arranged in oblique lines, which at the truncate end of each wing (or base of angle) follow its curvature. Each flower is surrounded by a roundish brownish cicatrix, then comes the rim of the calyx, thickened very obscurely, 4-toothed, then the petals, flat and valvate in æstivation, expanded, they are recurved, reflexed. Pet. triangulari-cordata viridescent. Stam. 4 cum petalis secernent iis opposite filam. reflexæ. Anth. magnæ biloculares introrsæ. Pollen triporat.

Ovar. e fundo cavitatis conicum, not projecting beyond the level of spadix.

Stylus sub 0. Stigma terminal simplex inconspicuum, bilocul. loculis 2 ovulat. ovulis erectis anatropis.

HAB. Malacca. In sylvis ad majora, Ayer Punnus.

This is a remarkable form, apparently allied to *Pterisanthes* of Blume, it is interesting as shewing a spadicose inflorescence, and venation analogous to that of *Kaulfusia*, each flower being surrounded by a net work and a ring of vessels, given off from the main branches. This also is interesting as shewing the nature of the cirrhi.

I have a *Vitis* in which a passage to this inflorescence takes place, the flowers being arranged on paniced spikes, the confluence of these would produce a spadix. But what is the venation in these? what is the cicatrix round each flower? what is the Perigone of *Pterisanthes*?

Fruit not seen.

OBS. Differs from *Pterisanthes* in hermaph. all immersed flowers want of involucre.

1. Plant natural size.

2. Portion of spadix, the flower to the right before expansion, one during expansion, and one after fall of petals to left.

Folia pinnata longe petiolata, petiolis ute pedunculus sursum (usque ad pinnulus) subincrassato et ad exsertionem (humi) rubro. Pinnulae $\frac{1}{2}$ vel $\frac{2}{3}$ verticillat. spathulatae glaucae, apice sæpius trilobae concavo-conduplicatae secundæ pinnularum mediarum foliola numerosivia, sed sæpius 4.

Panícula cymiformis amplicia composita patentissima, flexuosa pluries dichotoma* bractea squamiformis membranaceae ad basin cujusque ramificationis, semi-ampectens, adpressa concava.

* Not in the true dichotomous manner, but approaching to it because the terminal flower is most developed. It may be considered as dichotomous, one of the forks suppressed.

Pedicell sæpius elongati ad apicem subincrassati.

Calyx 3 sepalus, sepalis caducis oblongis concavis subpetaloideis rubro-fusco-tincti, imbricatis subvenosis.

Petal 6 biseriata æstivat. imbricata oblonga vel oblongo-obovata, patentia apice rotundata irregulariter dentata vel denticulata lutea decidua.

Stam. totidem opposita, hypogyna. Filamenta ad antheræ extrorsæ adnatæ biloculares valvatæ, valvis inæqualibus interior angusta non secedens, reflexa cito, exterior magna secedens ab omnibus adhesionibus apicali tantum excepta incurva revoluta, persistens.

Pollen oblongum, glabrum immersum primo effundit massam mucilaginosa aspectu tunc cito rumpitur.

Is the outer coat soluble in water, I think not, because after bursting, the pollen retains its color, and the inner coat is always colorless.

Ovarium ovatum uniloculare, carnisve subirregularibus alis pluribus sæpius ad ejus apicem bifurcatis munitus, sutura placentato distinctissimo crasso, stylus subnullus, stigma repando undulatum in massam capitatum dispositum.

Ovula pauca 5-7 placentæ parvæ basilari e sutura placental distinctur affixa erecta, interiora longius pedicellata, tegmine bina, foramine hilum prope.

Fructus non viscus.

1. Plant nat. size.
2. Bud.
3. Flower.
4. Pistillum surrounded by stamina.
5. Inner view of stamen, before dehiscence.
6. Outer do. of one dehiscing.
- 7, 8, 9. Anthers after dehiscence.
10. Pollen.
11. Do. immersed in water.
12. Pistillum outer face of.
13. Do. inner, shewing distinct placental suture.

14. Pistillum laid open along outer face.
15. Placenta and ovula, at α base of placental suture.
16. Long section of ovulum.

A curious plant, two species occur about this place, the leaves generally emerge from the ground at some distance from the inflorescence. The other species is very like this in inflorescence, but the leaves are simply pinnate. The inner valve of the anther *i. e.* the one not reflexed as valve, is the smaller, this is, I think always the case; but why the peculiarity of dehiscence depends upon this inæquallity is another thing.

GEN. CHAR. Calyx 3 sepalus, cuculus. Pet. 6 biseriata. Stam. totidem antheris valvatis. Pollen mucilaginosum, ovarium alato-carinatum, ovula plura, stigma undulato-capitatum. Herbæ perenniis cauli subterraneo-radiciformi tuberosa foliis pinnatis, glaucis ramulis secundis oppositis vel semiverticillatis. Panicula cymosa aphylla, flores majusculi lutei.

Species prima. Caulis areolis indistinctis pinnulis oppositis, late oblongis apice trilobis pinnula sæpius brunneo transverse fasciatæ.

Sp. secunda. Caule areolata pinnulis 4-6 semiverticillatis spathulatis apice 2-3 lobis conduplicatis. Præcedente paullo major. Pinnulæ fasciatæ.

CYATHOTEMMA.

Cyathostemma viridiflora, Pl. DCL.

Cymis caulinis ex axilla veluste dichotomis patente nutantibus, dense ferrugineo-pubescent. Bractea oblonga concava dense ferrugin. pubes ad ramum singulum, unoque paullo supra medium pedicellorum clavatorum.

Floris basis planiuscul. sub 3-gona ambitu sepalis 3 late cordatis patentissimis e basi subreflexa, ferrugin. pubesc.

Petal 6 duplici serie incurvato connivent and in corolla depresso urceolat. disposit. Pet. basi gibba vel subreflexa, æstivatione apicibus valvata, carnosus coriacea viridescencia ferrugineo-pubescent præsertim secus margines punctataque.

Stam. plura, cuneata, connectivo apice dilatato, projecting forwards over the apices of cells and arranged in a convex disc angulato-ferrugin. pubescent. loculis introrsis linearib. completis longit. dehisc. Pollen læve? e porosum ovato-rotundat.

Pistilla plura centralia, apices on a level nearly, with the upper edge of the corolla, angulate cylindraceæ dense pubesc. ferrugin. stylus sub 0, stigma magna oblonga glabrum emar-

ginat. ovula plura biseriata anatropa. Placentæ processus membrana distinctus inter series ovulor. interject.

This appears intermediate between Anonaceæ and Schizandraceæ, but I have not seen the fruit.

The wood is remarkable, the pith is very small. Ligneous system white subcruciatly 4-lobed, sinuses of lobes concave, 2nd brown very thin opposite to angles of the white, but much developed and filling up the concave sinuses between the white lobes.

The vessels of the white lobes are large and frequently, the medullary rays are pronounced, complete and white in both systems, very large towards the circumference, and generally containing one or two linear faciæ both of white wood.

Medullary rays distinct continuous with back and medulla, the spaces between each *i. e.* the wood composed of fine dense fibres, and a subsingle row of vessels, (*scalarif.*), the brown part consists of transverse subundulated lines of woody fibre, and transverse oblong spaces filled with brown matter! These brown spaces are divided by septa, and probably the chief difference between the brown and white, is, that in the brown, the vessels predominate so much as to subdivide or break up the continuity of the fibrous part.

I know no anonaceous plant with a corolla like that of this one, although Artabotrys would resemble it, and several others if the lamina of the petals were absolutely abortive.

The flowers have no odour, but the usual aroma exists in the plant.

I only know the male flowers of kadsura or Sphærostemma, but this plant agrees with it in form of perianth corolla, in the bracteate padicel and in the valvate æstivation.

It is not however monœcious, and its ovaria, and anthers are decidedly (particularly the former) anonaceous, and so is the number of the parts of the perianth.

The wood, certainly tends to the menispermaceous structure.

Coniferous markings round or transversely oblong, exist on the larger vessels, while the cells are from end to end, and I see, appearances as if the markings were confined to oblong cells lining the scalariform ones, certainly so, that there would seem to be two forms of these cells, one simple membrane with a lining of coniferous marked cells, the others simply punctate.

UVARIA.

Uvaria mabiformis. Gr.

Scandens?

Ramuli flexuosi folia obconduplicata concava, oblongo-lanceolata vel ovata integra, obtusis emarginata, glabra exacte ut in Maba vel Diospyros subtus glaucescentia et minutissima reticulata. Pedunculi axillares solitarii, petiolor. longitud. deorsum curvati parce bracteati.

Cal. basi planiusculus profunde 3-partitus, the outline is nearly triangular from a very broad sinuses.

Pet. abbreviate valvate, exteriora cordata, crassissime præsertim apicem versus (sessilia) basi concav. centræque carinulata. 3 interiores multo minores oblongæ conniventes apices versus cohærent *unguibus approximatis*.

Anth. 00. sessiles cuneatæ extrorsæ truncato-capitulæ, the chief part of torus occupied by the petals.

Pistilla pauca sub o seriata ovaria glanduloso punctata ovula 2 basi solida superposita, stigmata are longish viscid subulæ $\frac{1}{2}$ less the ovaria, at first sight altogether Diospyraceous.

Aloor Gagah, Verupha, *July*, 1842.

The branches are greenish inner petals quite hide the genitalia, and form together an oblong 3-furrowed body, outer petals scarcely opening, exceedingly thick and tough obtusely triangular. taken together.

Uvariæ sp.

Ramuli albidī fol. distant. breve petiolat. oblongo-lanceolat. longe et obtuse cuspidata, atro-viridia coriacea integra glabris (v. 2 dariis exceptis) indistincte venosa.

Pedunculi axillares, ferruginei bractes pluribus, distichis, ferugineis basin versus, deorsum curvate. Fl. solitaria penduli magna, viridescens extus ferruginei.

Cal. basi planus areola obsolete 3-gona notat. (angles alternating with sepals) profunde 3-partitus laciniis 3 angular.

Pet. 6 carnea biseriate, 3 exterior triplo major sublanceolata, basi late glabrata vix concava, utrinque præsertim extus pubescent ferrug. 3 interiora sericeo-pubescent unguibus distantibus in conum super genitalia connivent cohærente.

Anth. sessiles cuneat truncat. extrorsæ bilocul. connect. occupying whole breadth of apex, numerous in several series, ovaria in conum disposita series, styles filiform clavate very long, twisted, cellular scarcely stigmatose.

Space between their bases occupied by a large mass of light brown viscum, which is probably the stigma.

In the young state the styles are merely incurved, dilated and compressed, truncate at apex, furrowed longitudinally the margins of truncate apex along the end of sulcus looking rather stigmatic.

Stamina disposed in a subdepressed globular mass.

Pistilla when torn up from base, shew there 5 distinct veins, 1 middle, 2 lateral. Ovula 4-6 plura uniseriata.

HAB. Malacca. Aloor Gagah, Verupha: *July*.

OBS. This is like the *Usesquipedalis*. It belongs to same squad as the *lutea*, but passing off, the limiting of the stigmatic secretion to the lower part of the style, and its congregation into a central viscous mass is curious, so are the long styles, twisted inwards almost involute, at the apex the fecundating sphacelation is intense at base of the styles.

Uvaria heteroclita. Pl. DCXLIX. Fig. II.

Rami flexuosi, hinc illinc crebre verrucis (lenticellis) asperato. Folia alterna breviter petiolata (petiolis basi haud articulatis supra planiusculis), ovula acuminata, distanter obsoleteque dentata carnosae glabra. Fructus dense capitulos globosos axillares nutantes dispositis sublente pedunculo crasso squamato.

Carpella (immatura) plurima dense congesta globosa, vel obcompressione majorem ovalia, angulata pressione, apice areolo sub 4-angulo plano quasi truncato notata, hinc et postice linea membrana brunnea sphacelata arcte adhærente cujus apex stylum brevem simulat. orta stipata, sessilia, unilocularia disperma.

Semina transverse sita, pendula reniformia hilo terminationem lineæ brunneæ versus directo.

Pulpa futura baccar. arcte semin. adhærent. Tegument. exterius unicumque crassum extus brunnescens subcoriaceum, intus cellulos. an e secundinio adnato.

Albumen arcuatum, molle niveum membrana cellulosa secundinia pallidissima brunnea inclusumcæque adhærens, apice excepto prolongatione intus tegumenta externe secus curvatura maxima profunda, quasi dimidiatum.

Membrana nuclei apicem versus tantum distincto, imo apice sphacelata cæterum cum albumine secundiniaque adhærens.

Embryonis rudimentem subobcordatum ex apicem nucleum pendens.

Ejusdem generis cum *Uvaria heteroclita* Roxburgh, Fl. Ind. ed 1832, 2,663. quæ forsitan eadem.

Suddyah: Feb. 2, 1836. Leviter aromaticæ omnia Anonacearum albumine integro excepto.

Uvaria (Aichmanthera) odorata.

Arbor. humilis cortice albescent. Ramis, ramulisque flexuosis subsimplicibus laxis, fol. alternis, in petiolis brevibus canaliculat. ovato-oblongis basi sæpius cordatis, aliquando obliquis cordatis, repandis integriis supra atro-virid. infra fusco-viridibus maculis nigrescentibus pallidis floribus axillaribus racemosis, pendulis, primo viridibus demum luteis, magnis odoratissimis. Racemis paucifloris, interdum 1-floris aliis abortientibus pedicellis velutinis articulatis basi bracteatis.

Cal. 3-partit. basi plana sepalis coriaceis lati-ovatis reflexis!

Cor. 6-petal. biseriatis seriei extima majora, lanceolato-lineararia longissima venosa. demum subrepanda marginibus revolutis.

Stam. 00, hypogyna, flam. sub 0, connectivum ultra antheram in apicula spinescente breve product. Anth. adnatæ introrsæ, stam demum brunneæ.

Stigmata turbinata capitulum aggregata: styli breves, ovaria plura 1-locularia, pluri-ovulata, ovulis 2 serialibus, carpella immature stipitata pyriformia, torulosa vel nec, baccata nempe pulpa repleta, seminibus 1-2 vel plura, transversis.

Pet. interior demum basibus conniventia! Genus distinctum *Uvaria* proxima distinguend.

Calycis sepala reflexa. Pet. interiore paulo minore. Anth. apiculo spinecente. Stigmata turbinata in capitulum ultra anth. productum, aggregata, ovula glabra, 1-locul. ovulis pluribus biseriatis, carpella glabra stipitata torulosa vel lævia, 1-2 sperma.

HAB. Mergui, culta: Oct. 1834.

The carpella in all apocarpous Anonaceæ? appear to be torulose if more than one seeded.

ARTABOTRYS.

Artabotrys malayanæ.

Ramuli, bright brick dust ferruginous. Folia oblonga basi oblique cordata, cuspidato acuminata coriacea, subtus glaucescentia et advenas ferrugineo-pubescent (uto petioli et inflorescentia).

Pedunculi axillares, 1-2 flores, foliis multo breviores, bracteis pluribus caducis fl. penduli lutei fragrant.

Cal. ultra medium 3-partitus, laciniis ovario triangulari patente ascendente. Pet. 6 longissima basi concava in globum conniventa, vix constricta linearia vix gradatim alternata ad apicem, extus pubescentia biseriata, valvata.

Inner three shorter much narrower, scarcely dilated at base, leaving between the claws open genitalia, a transverse section would be sub 4 gonate of the base 3 gonate.

Anthers sessile, outer series ones effete, inner extrorse with purple mucos, cells looking as if they only contained two rows of pollen, grains connivent.

Pistilla several disposed in a cone, the apex of which projects beyond the globe of stamens distinct, ovaria densely ferruginous villous surmounted by a longish stigmatic subulose ovula few 1 seriate.

Peduncles of fruit much thickened subnutant, carpella sessile on a $\frac{1}{2}$ spherical torus, cylindrical with a tendency to be torulose, 2-2 $\frac{1}{2}$ inches long, vertically multilocular, each cell with 1 seed, immature only seen, albumen ruminate.

HAB. Malacca Aloor Gagah, Verupha.

This belongs to the Artabotrys squad, known by the elongate valvate biseriate petals arched over the genitalia, and generally ? torulose fruits.

A sharp angle elevated line always ? decurrent from the base of the petiole, leaves above very nitent.

Fruit cell red sometimes somewhat angular fibrous, bac-

cate flesh sanguineous colours, seeds oblong ovate, greyish raphe complete obscure. Embryo basilar minute plates ruminating stout.

SPHÆROSTEMMA.

Sphærostemma Blumiana, Pl. DCLI. Fig. I. II. DCLIV.

Frutex ramis sublævibus compressiusculis flexuosis brunneis. Fol. altera exstipulata in ramis articulata, ovato-lanceolata acuminata cuspidata integra glabra carnosæ, semina pellucida contusa aromatica v. secundariæ irregulariter arcuata nexæ, pagina cæterum reticulata.

Flores solitaria axillares in pedicellis petiolos subæquantibus sursum incrassatis bracteate squamatis ! Bracteis imis in tegmentis exeuntibus. Alabastra globosa basi 5 bracteata bracteis inæqualibus 2 interioribus majoribus quorum una maxima, 3 exterioribus minutis ut hæ pedicellorum basi carnosus. Bractea maxima ut videtur postica.

Perianth imbricata distinctio corolla nulla, sepalis rotundatis, 10 sepal, sepalis inæqualibus exterioribus majoribus interioribus nanis, vel sepala 5.

Petala his alternantia interiora nana, æstivat. imbricata, 2 exterior, 3 interior.

Stam. 00, in disco conoideo elevato inserta, atrobilium Pini non male referentia.

Filamenta brevissima distincta connectivum præ aliis dilatatum transversum, maximum carnosum. Antheræ parvæ albæ biloculares adnatæ sed non per omnes longitudinem connectivum insertæ longit. dehiscentis, adeo dispositæ ut antheræ externa visibiles compositæ sunt.

Stamina spiraliter disposita alternatum opposita.

Of this I have only seen young buds, the anthers are very curious, at least as regards their disposition, the cells of each are of course owing to the great size of the connectivum very distant, but as if some approximation was ne-

cessary, they are disposed so that the cells of one anther are closely applied to the near cells of the two contiguous stamina.

The pith of this plant is remarkable for being traversed longitudinally by bundles of exceedingly dense irregular occasionally branched fibres. These fibres are semi-opaque containing either inside or out, amylaceous granules and consisting of a superposition of at least two fibrous tubes.

Between the wood and bark occur, 1st dense, but small cellular tissue, then a viscid matter, containing the rudiments of fibres, the cambium. The bark is perforated here and there with irregular inter cellular passages.

Aromatico-piperaceous smell, very like that of *Sedgewickia* hence I was led to look for coniferous markings. These markings are less developed than in *Coniferæ*, the disk being larger and always opaque.

The vascular system is very little developed, and consists of unrollable ducts of a great size, the fibres of which are occasionally mutually united along the middle.

The fibrous tissue is excessively dense, and external to the vascular, the fibres are of small diameter, and are of punctuated tissue the punctuations being in one or two series, in addition coniferous glandular punctuations are frequent, but apparently always in one row. The fibrous system immediately surround the vessels has occasionally, the limits of the fibres so incomplete, that the vessels appear as if contained in a tube, apparently very frequently perforated, and interspersed here and there with coniferous markings.

HYALOSTEMMA.

Hyalostemma sp. Pl. DCLIII.

MICHELIA.

Michelia champaca.

Arbor. elegans 40 pedalis truncato abscisso ad altitudinem 30 pedalem non ramosa.

Folia petiolata lanceolata subacuminata integra, subtus ad nervos sparsum pilosa. Petiolis basi vaginantibus, (nempe marginib. canalicule circa ramum productis,) a basin usque ad medium canaliculato superne sulcato, tantum canaliculo abrupt terminant.

FUMARIACEÆ.

FUMARIA.

Fumaria affinis, Pl. DCLVIII. Fig. I.

The flowers of *Fumaria* are highly irregular, in the first place, the calyx is very indistinct. The envelopes consist of two exterior scales, and four irregular leaves, all of which are carinate, the portion forming the carina being green, all more or less cucullate, and the uppermost one calcarato-saccate at the base. They are each provided with three veins, of which the central one corresponds to the carina, and in its direction the tissue is, in a marked degree longitudinal.

The male organs consist of two flat membranous compound filaments, three-toothed at the apex, each tooth bearing an anther, its veins are three in number of which the central one is most distinct. The lateral anthers are unilocular, the central truly bilocular all are extrorse. The pollen presents 4, and perhaps more grooves or pores,

The pistillum consists of a unilocular uniovulate ovarium ; an articulated declinate style, with 4 vessels, and a large stigma, consisting of two lateral subcornute processes, and between these, two rudimentary ones will be found. The vessels belonging to these are close together, so that at first sight, there would appear to be only three bundles, but pressure particularly at the apex of the style demonstrates the existence of 4. The four stigmata are opposed to the 4 leaves of the flower.

This structure is difficult of explanation.

The two scales may be bractæe approximated, closely to the flower, in which case the inflorescence if more developed, would—be dichotomous, and in this supposition, the two outer larger leaves will be calyx, and the two inner corolla, these being opposite to the two scales as they should be. Here however the alternation is interrupted the bilocular central anthers are evidently opposed to the outer leaves, but the lateral ones have no evident relation, although they may be traced to the sides of each lateral inner leaf or petal. The four carpellary leaves return as is very common to their proper relations, and are opposed to the leaves of the perianth.

The scales have so decided a relation to the bractæe in structure that I believe this view to be correct.

There seems to me, to be only one mode of explaining the anthers, these are bilocular, the lateral anthers being completely divided into two, in which case each anther would be opposed to the constituent parts of the envelopes.

This, I find is Lindley's view, who however shews that the alternation is quite correct, a circumstance which I had overlooked.

1. Calyx.
2. Petals.
3. Stamina.
4. Ditto.

The only objection to this binary arrangement is in the structure of the ovarium, this however may be of little importance if Papaveraceæ be taken into consideration. But if Lindley is correct in saying that all the 6 stamina are sometimes distinct, no explanation of the sort will suffice.

The opposition however resulting from this is so universal, that it is probable there are two series of stamina, it is besides more consonant with the situation of the bilocular anther to attribute it to pressure, rather than the simplicity of the lateral ones to dislocation.

Examined at a very early stage, when the lateral stamina are very nearly distinct and free, their situation is evidently in pairs opposite to each petal, there is at this period no appearance whatever of the simplicity of the bilocular anther. The situation of the loculi is such as would result from the complete division of a bilocular anther.

I see nothing in *Fumaria officinalis* corroborative of Lindley's notions as to impregnation, the horns of the stigma are opposite to the sepals, and cause the bulging out as it were of the bilocular antheræ. I can ascertain no twisting of the lateral filaments, all the anthers being without exception extrorsæ. The fact is, that the cavity in which the genitalia are confined is so limited that no peculiar means are necessary to counteract the defect in situation of the anthers, and impregnation is nearly universal. The anthers after dehiscence contract much in size, and shortly after this operation, they become removed from the stigma, which is then surrounded by the pollen.

Bocconia is said to be apetalous, if so, so may be Fumariaceæ, the development and origin of the envelopes is perhaps rather calycine than petaline, but the subject* is so difficult as to require extensive examination, Papaveraceæ cannot be well understood, the two-leaved calyx and 4-leaved corolla requiring satisfactory explanation. We might combine Fumariaceæ with Papaveraceæ because of Hypecoum which is another instance of incongruous inconsistency. If it ought to be done, then we ought to treat similarly all intermediate forms.

HYPECOUM.

Hypecoum sp. Pl. DCLIX.

Herba annua, tenera glaucescens, statura valde variabilis.

Radix fusiformis. Petiolis canaliculatis basi dilatatis.

Foliorum limbis pinnatis, pinnis sæpius alternantibus sub capillaceis pinnatifidis lobis bi-trilobis. Inflorescentia pluries dichotoma initio cernua. Pedunculi crassiusculi spithamæi interdum pedalis dichotomis ramis foliis 2 capillacei-pinnatifidis oppositis suffultus, ramulo centrale florigero nudo, this continues 2 or 3 times, one of the branches being more or less completely dichotomous.

Flos. expansus bilabiat. labiis rectis sinistrisque sepalis interior patentis deltoides cuspidatis concavis marginibus demum involutis. Petalis erectiusculis labiis biniis utrinque.

Flores laterales ultima foliolis eodem more divisio, stipata. Pedicelli subclavato fructuum cernui. Bracteæ binæ ovatæ, (sepala auctor. sepala sunt) sepalinæ glaucæ ad basin cujusque floris. Sepala 2 æstivatione incurvato-valvata, lato-oblonga apicem versus subcarinata, lutea initio viridia sepaloidea demum omnino petaloid decidua.

Pet totidem bracteis opposita ultra medium (structura singulari) sepalis paullo minora lobis lateralibus oblongis obtusis, centrale (pars antheriform vasc. uno lobis lateral ve-

nulosis. Potius, pedicelli partis antheriformis, alato lobat. lobis postea evolutis,) antheriformem brevi pedicellat. concava lamina pulchra fimbriata, demum recurva, carina obsoleta in centro lutea maculis parvis atro-purpur.

Bracteæ or sepals of terminal or central flower anticous and posticous of the lateral ones, right and left only.

Stam 4 anisomera, his petalis oppositis compositis, illis sepalis oppositis simplicibus. Filamenta carnosia complanata, rugosula, his (sepalinis) paullo brevioribus et $\frac{1}{3}$ angustioribus vasc. centrali unico illis petalis amplexis latioribus et longioribus (his) vasibus binis, quorum quoque ad marginem interna loculi cujusque currit.

Antheræ adnatæ oblongæ loculis lateralibus omnes biloculares, et statura excepta nulli modo different. the septa of larger ones are more complete.

Pollen ovatum medio plicatum glabrum. Ovarium 4 gonum, oblongum sursum in stylum curvatum centro sulcatum attenuat. Stigma bilobum et secus sulcum stylo decurrens, fol. carpellam bina (right and left,) uniloculare, placentis binis anticis posticisque indistinctis ovulis biseriatis alternant pendulis, structure ordinarie, foram. subconspicua ad apicem ovuli deorsumque spectantes. Fructus siliquiformis, deorsum curvatis, vel nutant subteres utrinque attenuat.

This is a singular plant evidently belonging to *Fumariaceæ*.

The outer scales or sepals of some authors are perhaps better viewed as bracteæ, to which in some plants of the order, they are extremely akin in structure and form. They may perhaps be considered as bracteæ from viewing the strictly dichotomous nature of the inflorescence in some, and in this case *Fumariaceæ* may be expected with ternarily subaggregate flowers, and without these outer scales.

The sepals have a curious æstivation, incurvato-valvato, it is only at an advanced stage of development, that they put on the petaloid appearance. The petals presents the

most curious appearance, and one which shews obviously a tendency to pass into anthers, indeed being the expansion of the flowers, casual observation might easily suppose that they were a bona fide part of the male apparatus, which at any rate they certainly aid, for the fimbriated lobe embraces the anther, and thus prevents the dispersion of the pollen in the wrong direction. Its appearance or resemblance to an anther is likewise pointed out by the carina, which may be seen on its centre of its inner surface, and is analogous to the septum of a locellus of bilocular anther.

The structure of the anthers is curious in as much as it points out, that there is a strong tendency to the existence of bilocular and unilocular anthers in the family, and tends to disprove the idea that all are unilocular, some becoming bilocular by adhesion, for there is no proof whatever that those opposite the sepals are compound.

The alternation of the parts remains to be explained.

We have two outer scales, with which 2 sepals alternate, opposite the scales a trilobed body of petaloid nature, and opposite these two compound stamina and the sepals 2 simple stamina, my idea is this, that the outer scales form part of the calyx, which is hence biseriate. The petals are represented by the lobes attached to the antheriferous body, from which their venation is distinct both in nature and origin.

1. { Sepals.
Sepals.

2. { Petals.
Petals.

Stamina.

Stamina.

Stamina.

Stamina.

Corroborated by development, the antheriform part formed first and cæteris paribus the soonest developed, the stamina opposed to the large sepals open first.

The stamina are 8, of these four are opposite the sepals so understood, and 4 to the petals, the two outermost of the outer series are opposite the scales, and are barren, the two next are simply bilocular, according to the tendency shewn this way by the antheriform body, testa ejus carina. The four inner ones, are united two and two are obviously opposed to the lobes of the antheriform body or petals.

Thus viewed, the only deviation from the due alternation exists in the carpellary leaves, which ought to be opposed to the scales or outer sepals, but the subject of the relation of these leaves to those of the calyx demands rigid investigation.

Fumariaceæ are thus quaternary and the Hypothesis of Dr. Lindley, so far as *Fumaria* is concerned is corroborated. If the above view is correct the outer scales most form portion of the calyx, because as these in the case of their being bracteæ have nothing whatever to do with the flower, there would be no reason for the opposition of the outermost stamina with them.

What might be the case in a plant with genuine opposite leaves is another thing, there is nothing discordant with the assumption of a flower of two opposite bractes, and two sepals, with two stamina opposite these bractes.

Char. generis. Sepala 4 biserialia, exteriora minora. Petala 2, triloba lobo medio antheriformi-fimbriato. Stam. 4, 2 sepalis majoribus-2 petalis opposita, antheris bilocularibus.

Fructus seliquiformis.

Herba tenera fragilis, foliis pinnatis pinnis pinnatisectis, inflorescent dichotoma, floribus bilabiatis luteis.

1. Plant.

2. Alabastrum.

3. Flower, inner petaloid sepals removed.

4. Bud, sepals removed, the two lateral lobes represent the petals, the inner, the outer squamiform sepal.

5. Bud larger sepals removed, one of the petaliform com-

- pound bodies slightly displaced the other in situ, and enclosing one of the compound anther.
6. Petaliform compound body viewed in front shewing the distinct venation of the parts, and the carina representing the septum of a locellus.
 7. Flower after expansion, outer sepals, and one of the petaliform compound bodies removed, the other in situ, anthers withered as well as the apex of the filaments.
 8. Do. viewed in front.
 9. Petaliform compound body, veins not shewn except on pressure.
 10. Antheriform lobe in front. 10. Do. laterally.
 11. One of the simply bilocular anthers, opposed to the larger sepals.
 12. Larger anthers, each composed of two simply unilocular ones opposed to petalisform compound body, the difference in their venation shewn.

 18. Ovulum.
 - 18a. Do. long section, second coat not distinct.)

RANUNCULACEÆ.

General Remarks.

In this order, there is a great tendency towards the transformation of petals into stamina, the tendency is at its minimum in those genera which have petals of the ordinary form, at its maximum in those in which the petals are cucullate, the intermediate form existing in those species in which a

scale is present fixed near the base of the petal, or when the base, itself as glandular.

It is to this excessive tendency, that the want of petals in *Clematideæ* is to be ascribed, and hence we may be led to expect the existence of species belonging to this section in which the transformation is not altogether complete, and this will be proof furnished by induction.

The ovula have only one tegument, which is testa. The closeness of the affinity of *Umbelliferæ* to this order does not appear to me very satisfactory.

It is true, that there is a remarkable coincidence in habit, but not much more than there exists with certain *Compositæ*, such as *Bidens*, and *Coreopsis*. It is with this great family, that it seems to have very striking affinities, it approaches to it beyond all doubt in the nature of its inflorescence, in the frequent separation of sexes and above all in the difference, in formation between the flowers of the ray and the centre of the umbel, in the adhesion of the calyx with the ovary, in the reduction often even to obliteration of the former organ, in the number of styles and of stigmata.

It certainly has marked differences of which the separation of petals is the most important, for monopetalism may be regarded as at its maximum in *Compositæ*. In the bicarpellary nature of its ovary it also differs, but such should be the structure of *Compositæ*.

The different direction of the ovule is not much to be depended on, since in *Opercularinæ*—a tribe acknowledged by all to be closely allied to *Compositæ*, the seeds are pendulous. The same remark applies to the presence of albumen, with this difference that in *Opercularinæ*, the embryo is axile, in *Umbelliferæ* basilar. That this minute point is not of much value, as indeed might be argued a priori, is indicated by the structure of the seed of *Lardizabaleæ* as compared with *Menispermæ*.

The first tendency towards suppression seems to take place in *Vaterianææ*, in which the abortive cells are not quite

obliterated, and in some of which the ovary would appear to be really simple. The same may be said of Dipsacæ, but this statement of simple ovary is opposed to an observation of Mr. Brown, viz., there is no instance known of a simple inferior ovarium.

I think, it can scarcely be doubted that the real relations of Umbelliferæ are in this direction, the only strong objection being its polypetalism. It must not be forgotten that if there be a law of representation in the vegetable kingdom such as there is in the animal, that the relations of Apiacæ with Ranunculaceæ are quite in order.

The presence of a minute embryo, at one extremity of the albumen is only important as indicating a lower degree of organisation, the formation of albumen being such as to impede the cotyledonary growth of the embryo. It follows as a consequence of this, that the situation of such an embryo must be at the apex of the nucleus.

The idea entertained by some botanists of albumen always pre-existing, which has led Mr. Lindley to suppose, that in those cases in which it is slight in quantity it is merely a residuum, is erroneous. If it were true, albumen should be distinctly traceable in all the stages of the evolution of an exalbuminous seed, this however is not the case, and the distinction between an albuminous and exalbuminous formation is easy enough.

The dilatation of the base of the petioles is not a mark of a valve, it exists for instance in Rosacæ, and in Compositæ etc. Even in the opposition of the leaves certain species *Spananthe* for instance agree with Compositæ.

If my views be correct, we may expect to find Umbelliferæ with tendencies to the formation of pappus.

I may remark, that the value of the minute basilar embryo is completely destroyed by Araliacæ, in which DC affirms it is nearly equal in length to the albumen, Lindley notices this, but not the discrepancy of his own account in which it is given as in Ranunculaceæ. It is through this

order that Umbelliferæ are related to Sambuceæ, curious enquiries suggest themselves concerning pappus. Vateriana would lead as to suppose, that this organ is more developed according as the flowers are submitted to more or less mutual pressure. This subject can however only be cleared up by ample examination, many exceptions would appear to exist to the idea in Compositæ.

The abortion of the ovaria ought to be examined, particularly as to its constancy with relation to the parts of the flower, because this may suggest other affinities with Composita.

I am inclined to doubt the affinity of Vites with Umbelliferæ, it is an instance rather of analogy. The inferior calyx, valvate corolla, and particularly the position of the stamina relatively to this, the plurality of seeds and their direction are all important marks of difference.

I could shew with equal reason affinities with an order, usually, supposed to be far removed, Cucurbitaceæ, in habit articulation, tendrils, (although these fulcra perhaps have not the same origin in the two organs,) in polypetalism, and opposition of stamina.

Through Sambuceæ they pass into Caprifoliaceæ, in some of which a degradation of calyx occurs, and to Saxifrageæ through Hydrangeæ.

In the inflexion of the stamina during æstivation Vateriana agrees additionally with Umbelliferæ. In this genus there is tendency towards Dipsaceæ, which have connate filaments, indicated by the union of the filaments towards the base where they are adnate to the corolla. The effect of this is the formation of a sort of septum, which with the gibbosity gives somewhat the appearance of a tendency to calcaration.

The æstivation is imbricate, the venation is curious, the primary veins being luminary and axile, mutually giving off cross branches which run across the sinuses, before arriving opposite to each, they give off a branch which however does

not reach to the termination of the axile one, which is clavate, (I have badly explained this.)

The ovary has 6 nerves, three of which occupy one side, two the margins, and one the opposite side, the intervenia are shortly hairy.

The ovula except in situation much resembles those of Compositæ, and like them they are reduced to a single tegument adhering uniformly and as it were identified with the nucleus.

The subsequent coat formed is the embryonary sac, in its earlier stages it is very apparent, but in the perfect seed adheres with the outer coat, with which it is likely to be confounded, it is developed from the base of the nucleus. It has precisely the same structure as the corresponding coat of Compositæ, which is at once known by the areola being occupied with masses of grumous tissue.

The endocarp? subsequently becomes soluble and separates with the seed, it is coriaceous inclining to bony. It might at first sight be mistaken for the testa, but its being evascular, and the presence of the raphe or the inner lining or envelope are sufficient proofs of its nature.

In this *Vateria* is the reverse of many and perhaps most Compositæ, in which the immediate envelope of the seed is derived from the embryonary sac, the testa generally separating with the fruit, to the inner paries of which it indeed adheres. The cotyledons are alternate to the raphe.—The style has three vascular fascicles.

Is not the double pappus analogous to the involucrel of certain *Dipsacæ*.

The assertion, that *Gentianæ* have hypogynous disk is not correct, I find in a species of *Gentiana* common in Bootan, that it is a good deal developed, and distinctly divided into 5 lobes, which lobes as might be expected alternate with the fertile stamina or in other words are opposite to the segments of the corolla, we may hence expect to find decandrous *Gentianæ*.

The additional lobes of the corolla alternating with the true lacineæ are mere processes of the sinuses or rather each petal may be esteemed as being 3-lobed, the lateral lobes of two distinct petals being frequently completely connate. This latter view is pointed out by their occasional emargination, the former by the fact that they are completely evascular.

I once had an idea, that in all truly monopetalous corollas, the veins would run both in the axes of the component lacineæ, and in the axes of the sinuses, but *Gentianæ* at least the species alluded to, is an exception to the contrary, to such a degree that no vascular fascicle is even furnished to the stamina, while the lacineæ are provided with three distinct fascicles, which have in the lamina, the ordinary distribution.

In this respect it agrees with *Villarsia*. The locule of the anthers are after dehiscence completely opened out and placed back to back, they are in this state much contracted. They recover their original dimensions and form by immersion, and what is curious, lose immediately their red colour.

The last point is, that the whole surface of the ovaria may bear ovula, of this the species alluded to affords an example of baccate fruit. One Cucurbitaceous plant is indeed so like a *Vitis* (*Cissus*) that it is impossible to perceive any difference until after a close examination.

To return to *Ranunculaceæ*, the tendency of the order to produce petals passing into stamina is borne out by the study of the other nearly allied orders, such as *Magnoliaceæ* *Nymphæaceæ*, etc. but the transformation may be assumed in these to be retrograde. It will be a curious corroboration if retrograde metamorphosis be found to be more complete than progressive.

ACONITUM.

Aconitum lethale, Gr. Pl. DCLX. Fig. III.

Cal. 4-sepalus, sepalis ovatis caducis æstivatione involuto valvatis marginibus tomentoso-velutinis.

Pet. 12, si pauciora in stamina converta, clavata viridia.

Stamina circiter 24, an semper biserialia, 1 cujusque seriei cuique petalo opposito. Anth. subsessilis, adnatæ lineares, introrsæ longit. dehiscent, connectiv. carnosu luteum.

Ovaria 10, 12, 18 seriea stipitata, stylus filiformis brevis stigma ovata obliquum. Ovar. 1-loculare, 1-ovulat. ovulo pendulo ab apice loculi, foramen hilum prope tegumenta ovuli distincta.

HAB. Mergue. In sylvis Ins Madamaca : Dec. 1834.

APPENDIX.

THE FOLLOWING NOTES HAVE BEEN ACCIDENTALLY
OMITTED UNDER THEIR PROPER HEADS.

1. *Ocimum.*

Floribus albis, odor. suaviss. Cal. tubo brevi inæqualiter 5-dentat. sepala postice reniforme margines nempe utrinque productæ, dentibus 2 inferior longioribus angustioribusque.

Cor. infundibulif. bilabiat. lab. super. maximo 4-dentato. inferior lineare oblongum, apice denticulat. Stam. didynama deorsum flexa par superior longiorisque, basi versus dente retrorsu spectanti pilosa. Filam. exserta subulata. Anth. reniform. ovatæ, 1-locularis, stylus filiformis basi purpurescens apice bifidus, stigmata simplicia. Ovaria ordinis nempe e carpellis 4 basibus versus cohærentibus, carpellis 1-locularibus, 1-ovulatis, ovulis erectis.

Didynamia anomalis pare supera nempe majore longioreque, alternatio stamina ut sequenter par inferum edentatum, utrinque labii inferioris oblonge, par superum, inter dentes laterales, et 2 centrales, lab. super 4-fidi, quinte si ad esset, inter dentes duos centralis.

Credi pilosa caulibus tetragonis. fol. ovatis, serratis pellucido-punctat. Inflorescentia verticelat. racemosa bracteata, floribus ternis in axillis cujusque bractæ, pedicellis nutant

HAB. Mergue. In ruderatis Madamaca: Oct. 1834.

2. *Decastrophia inconspicua.* Pl. DCXIII. Fig. IV.

Frutex scandens, foliis longiuscul. petiolat. petiolis utrinque attenuatis, exstipulat. alternis oblongo-ovatis, basi subcordatis palmatisque 5-nervus acuminatis repandis subtus glaucis, paniculis racemosis, racemisve axillarib. petiolis

brevior, floribus minutiss. lutescentibus viridi. Bractea minima ovata ad basin pedicello cujusque.

Cal. in tubo subturbinato ovario adnat. limbo brevissim. 5-dentat. Pet. tot quot dentis calycinæ iis alternant. disco epigyno inserta acuta ventra reflexis patentia, æstivatione valvata, marginibus dorsisque ad apices glandulosa.

Stam. totidem petalis opposita cum iis inserta. Filam. brevissima petalis basibus leviter ad nexis utrinque glandula viridescens apice pilifera petalis adnata stipata. Potius petala basibus 2 glandulosa glandulis sessilibus apice piliferis, stamina cuique pari interjecto. Anth. bilocul. adnatæ, longit. dohiscent.

Discus epigynus luteus integer cicatricibus petalorum albidis, stylus breviss. Stigma 3 capitata papillosa, Ovar. 1-loculare, 3-ovulat.

Ovulis pendulis, foramen hilum prope.

Olacineis affinis ob petalorum valvationem appendicularique, ob ovarium ovulaque pendula distincta ob ovaria inferum.

HAB. In sylvis intra Mergui et Beiktown: Dec. 1834.

Cirrhis oppositifolia, Omnia fere Rhæmnearum et præsertim Gouaniæ affinis: Discrepant ovar. 1-loculare, 8-ovulat. ovulique pendulis, anne potius Santalaceis affinis sed placenta centralis.*

3. *Pierardia*, sp. Pl. DLXXXV. A. Fig. XV.

Arbuscula dioica inflorescentia frequentius e trunco ortis, paniculata, paniculis racemosis floribus parvis lutescent sæpius 3 in pedunculo quoque. Pedicellis brevibus, pedunculus excedentibus adjunctionem articulatis, bracteolis minutis ad basin cujusque floris bracteis (ad basi pedunculoso) lanceolatis.

Perianth. (lataque panicula velutina) 4-sepalum, sepalis

* An Mackaya, Arnott. modocopsis Gr.

subæqualibus æstivatione imbricatis, dorso præcipue ad apices cellulis albidis barbatulis, concavis, intus cellulis oblongis inflatis bullatis.

Stam. 4-6 interdum plura hypogyne, alternatione nulla, aliquis nempe sepalis oppositis, aliquis alternant in 6 sepalosis, fere omnia, alternantib. filam. brevib. subincurvis. Anth. bilocul. longit. lateraliterque dehiscent. Stylus breviss. crassus. Stigma peltata plana, cellulis iisdem barbatulat Ovar. solidem abortiens.

Fructus edulis et fructus Burmannos inter fere optimus in cellulæ bullatæ materia grumosi repletæ glanduliformes.

HAB. In sylvis densis montanis Madamacca : Nov. 1834. Folia abnormalis.

4. *Cryptocarya rubiginosa*.

Arbuscula, trunco gracili altius ramoso ramulis crassis compressis, petiolis foliorum nervis mediis bases versus pedunculis pedicellisque plus minus ferrugineo-velutinis, fol. breve petiolatis alternis, ad apices ramulorum confertis maximis, longitud. 8-10 uncialib. diametro 3-4 oblongo lanceolat. acuminat. subintegris coriaceis subtus glaucescent et reticulatis, petiolo interdum ad apicem inferne glanduloso. Racemis axillaribus paniculatis, nempe ramulis inferior, 2-3 floris, petiolis duplo longiorib. floribus inconspicuis lutescente viridescentib. odoratis.

Per. connivens, 6-sepala, sepalis ovatis dorso plus minus ferrugineo-pubescent-exterior æstivatione valvat. interior imbricat. Stam. 3 serialia, seriebus duabus exterior introrsis, staminodia 2 serialia 9, omnino libera nec filam. stipantia, carnosiss. angulat. subantheriform lutescente omnia breve stipitat. filam. pilos. Anth. bilocellat. Ovar. ovat. 1-locul. 1-ovulat. ovulo pendulo ab apice loculi, foram. superum hilum versus, stylus subulat. stigma subsimplex.

Stam. 6 exterior, per paria utrinque filamentor 3 interme-

dior vel sepalis interior opposit. adjecta sed libera 3 interior samini- b. exterior oppositis et interioribus alternantia.

HAB. Mergue. Ad summitat. collis Palor. Jan. 1835.

5. *Vitex elegans.*

Arbor. humilis, ramulis ad apices foliosis, petiolis pedunculisque ferrugineo-pubescent, fol. longe petiolat. quinate digitat. foliolis juniorib. ovato-ellipticis subintegris, subtus reticulat. petiolis petiolulisque supra canaliculat. Cymis axillaribus divaricat. petiolos. excedent. pluries dichotomis, ramis ramulisque quadrati-compressis. Bracteis parvis membranaceis deciduis. Floribus numerosiss. elegantibus, suave odoratis.

Cal. tubulosus brevis, breviter 5 dentat. persistens. Cor. bilabiat. tubo calyce excedent subinflat. lab. superior bifido lateralibusque albidis oblongis reflexis, 9 5 medio, lab. infer. porrecto, obovato spathulato pallide cœruleo basi lutescente pulchra barbata, barba purpurasc. Filam. didynam. pallide corulia, glanduloso-pubescent parceque pilosa. Anth. atropurpureæ transverse dehiscent. Pollen alba stylus ejusdem coloris in filam. Stigma bifidis. Ovar. biloculare, placentis nempe accretis loculis 2 ovulatis, ovulis pendulis ab apicib. loculor. foramen inconspicua interior.

HAB. In horto meo, beato Mergui: March, 1835.

Æstivat. imbricato, lobo medio lab. inferioris intimo! labi super extimo. Pet lab. inferior articulat. sublente $\frac{1}{10}$ minute punctulat.

6. *Chionanthus terniflorus.*

Arbor. mediocris, ramulis alternantia compressis simplicibus fol. ovata obovatave, acuminata integra subrepanda, vix coriacea, subtus pallida, venis secundarius distinctis et distinctæ intra marginem arcuata nexis.

Inflorescentia axillaris spicato-glomerata, sæpius e capitulis, 2 lateralibus, 3-floris, spica terminata 5-floro, floribus 3 summis capitulatis, vel terminatis tantum adest.

Pedunculus pubescens petiolis 3 linearibus duplo longior florem parvi inconspicua inodora, omnes terminalis excepta bractea parva suffulta, alba calyx brevis, admedium 4 partit. persistens. Cor. dipetala, petala ultra media bipartita, lacinae lineares, obtusæ involuto-concavæ, linea junctionis evidens, ideoque e 4 conflata, petalis in platangibus duabus lateralibus accretis.

Stam. basi utriusque plalangis inserta, fissura opposita. Filam brevissima, connectivum carnosum. Anthera adnata ovata, extrorsa bilocularis loculis longitud. dehiscent medio longitudinaliter septa flores demum planis. Pollen album ovata sulcat.

Ovar. subglobosum biloculare, ovula bina cuique loculo collateralia pendula e axillis sublageniformia ob collum exsertom. stylus ovaria longitudine subulatus, ovarium pubescens stigma bifidum, demum connivens divisiones anticæ posticæque ideoque his sepalis nec petalis opposit.

Fructus no isus.v

HAB. Assam. Sudiya prope ripam Burrumpootur: *April* 15th, 8836.

Chionanthi species dichotoma Roxb. fl. Ind. 1. 107, Linociera est. Intermedias inter Chionanthem et Linocieram. Structura irregularis ob oppositione stigmata cum sepalis.

7. *Ligustrum punctatum*.

Arbor. majuscula, 20 30 pedalis. Folia opposita, oblongo lanceolata acuminata obtusa, integra coriacea, pellucido-punctata, venis subintra marginalibus, juniora sparsim pubescentia. Flores paniculati inconspicui lutescentes subsessiles, plerumque ternatim aggregati. Paniculae terminales pubescentes, ramulis divaricatis. Bractea lanceolato-foliacea pubescens ad basin cujusque ramulis. Bracteola linearis cinque flori.

Cal. tubulos. pubescens 4-dentat. dentibus rotundatis, 2 lateralib. paulo majoribus. Cor. infundibulif. tubo obtuse quadrangulari, limbo 4-dentato, dentibus erectis obtusis, subcucullatis. Stam. 2 epipetala. Filam. breviss. basi corolla affixa petalis 2 alternantia. Anth bilocul. longitud. dehiscent. Ovar. ovat. 2-loculare, loculis 2-ovulatis ovulis pendulis foramen ad hilum. Stylus sub 0. Stigma capit. transverse sulcat.

Æstivatio corollæ valvat. corolla exserta.

HAB. In sylvis circa Molamyain: Dec., Jan. 1834.

8. *Osyris rotundata*, Pl. DCXXVII. Fig. 11.

Frutex volubilis, ramis ramuloso-flexuosis viridibus. Foliis alternis obovatis in petiolum attenuatis junioribus spathulato-obovatis carnosius integerimis glaberrimis obtusis basi 5-venis.

Floribus axillaribus parvis viridibus aggregatis pedicellis bracteolatis sæpius unifloris interdum racemiformibus.

Filam. breviss. Anth. composed of two subreniform loculi placed obliquely.

Calycis tubus subglobosus, laciniis lata ovatis erectis vel etiam conniventibus stylus per brevis. Stigmata 5 parvis, radiantia:

Ovarium subbaecat.

Discus epigynus parum elevatus concavus sub 5 gonis.

Placenta infra centrum mammilliforme ovulis 5 circa basi radiatum affixis deorsum spectant nuclearum apice sacculi embryonis globoso $\frac{1}{2}$ exserto.

Bacca drupa initio rubra demum atro-perp. urceolata, tubo globoso, calyce immutato et coronata.

Pyrena apice mammillata 5-6 sulcata angulata, angulis rotundatis.

Semen 1 albumen pyrene profunde intrante 4-5 divisum, lobes of albumen on a transverse section obcordate.

HAB. Malacca. In sylvis secus litora Daris: Tangong cling.

Vegetation peculiar chiefly of *Eugenia* trees, with one or two *Guttiferæ* as *Calophyllum*, *Garcinia*.

A *Thibaudia* very common as a shrub, *Dalbergia*, *Premna*, *Dodonæa* rare, *Hoya grandiflora* alia.

The above *Santalaceous* plant is very much like one, from mount Ophir, Pudhan Bhattoo.

This is distinguished from the other *Malacca*, species by its fleshy, scarcely coriaceous leaves, by the aggregation of the female flowers in the axills, and by the shape of the calyx, especially in its young stages.

Osyris folis carnosus vix coriaceous, floribus fæmin. aggregatis, alabastis turbinatis, calycis tubo cito globoso.

There also appear to be no hairs at the back of the stamina.

9. *Strophanthus scandens* ?

Frutex scandens ciliis interpet. 00, fol. opposit. breve petiolatis oblongo-obovatis leviter repandes, cuspidato-obtuse acuminatis subtus albidis venis secundariis conspicue arcuati nexsim, venis cæterum parum elevatis vel cymis terminalibus multifloris gradatum.

Pedicellis brevibus robustis sepalis e basi gibbo convexo, longe acuminatis.

Cor. contorta, nfundibule tubo media constricto fere unciali. Fauce aperta coronata squamis petaloideis bipartitis cum laciniis alternant.

Filam. libera vix 0. Anth. subsagittatæ connectivis longe in setis productes, conniventibus subtortes, filamentos in adhering parts above the middle suddenly thickened lower $\frac{3}{4}$ of outer cells empty. Inner cells of another very unequal. Stylus robustus infra facies stigmatos annulatus supra in conum product. Ovarium biloculare cyrthandiform placentis revoluta involuto, in pagina extrorsa ovuliferis.

Folliculi maxime like horns, oblique divaricat. apice obtuse exeisi.

HAB. Malacca. Ayer Punus in thickets sp. formosa.
